Abstract: Recently evidence has been presented for the production of an  $I=5/2$  nonstrange baryon resonance of mass  $\cong 1640 \text{ MeV}/c^2$ , in the reaction  $\pi^- d \rightarrow (p) n \pi^- \pi^- \pi^+$ . With much greater statistics, our data for the charge-symmetric reaction fails to show any evidence for such a resonance.

Benvenuti et al.<sup>1)</sup> have reported confirmation of an  $I = 5/2$  baryon resonance of mass  $1640 \text{ MeV}/c^2$  previously seen by Banner et al.<sup>2)</sup> It is the purpose of this paper to present equivalent data with greatly improved statistics, showing no enhancement in this mass region.

Benvenuti et al. present data on the reaction

$$\pi^- d \rightarrow (p) n \pi^- \pi^- \pi^+ \quad (1)$$

at an incident pion momentum of  $2.26 \text{ BeV}/c$ . Here (p) indicates that the final state proton does not take part in the reaction. 2447 3-pronged events (with protons of momentum too low to produce a visible track in the bubble chamber) were analyzed in their paper. They report a narrow ( $\Gamma \leq 60 \text{ MeV}/c^2$ ) peak in the  $n \pi^- \pi^-$  mass spectrum, which is enhanced to 4 standard deviations when the momentum transfer from the beam to the  $\pi^+$  is restricted to be less than  $0.6 (\text{BeV}/c)^2$ . They also make cuts which indicate that the peak may decay via a  $\Delta^-(1236)\pi^-$  mode.

We have analyzed  $\approx 16000$  4-pronged events from the reaction

$$\pi^+ d \rightarrow (n) p \pi^+ \pi^- \pi^- \quad (2)$$

at incident momenta between 1.1 and 2.37 BeV/c. By charge symmetry this reaction is identical in its description to reaction (1); however, these events admit a better mass resolution than the 3-pronged events of reference 1. The events analyzed have been selected to have neutron laboratory momentum less than 300 MeV/c, to insure that the neutron is a "spectator" to the collision. We have also excluded events with confidence level for reaction (2) less than 1 %. We estimate that the contamination from other final states is less than 5%.

Our data has been divided into two intervals in beam momentum; the exposure size for each interval is about 7 events/ $\mu$ b. Interval I contains momentum settings at 1.10, 1.30, 1.52, 1.58, and 1.70 BeV/c; interval II contains momentum settings at 1.86, 2.15, and 2.37 BeV/c. The latter interval spans the momentum settings of references 1 and 2.

Figure 1 shows the  $p \pi^+ \pi^+$  mass spectrum; the shaded events are those for which the beam-to- $\pi^-$  momentum transfer is less than  $0.6 (\text{BeV}/c)^2$ . We note that this figure is equivalent to figure 1a) of reference 1. We see no enhancement at or near  $1640 \text{ MeV}/c^2$ , either in the raw data or after the momentum transfer cut. For completeness, Figures 2 and 3 show data corresponding to figures 1b) and 2 of reference 1. Selecting  $\Delta^{++} \pi^+$  events (Figure 2) does not produce an enhancement, nor does excluding  $\Delta^{++} p^0$  events (Figure 3).

We note that the momentum transfer cut made by Benvenuti et al. and reproduced in our Figure 1 would enhance the production of an assumed  $I = 5/2$  baryon resonance if it were produced via the exchange of a meson. However, in this case the meson would have to be doubly charged. A more likely exchange mechanism for production of an  $I = 5/2$  baryon in these reactions would be  $I = 3/2$  baryon exchange. We have also made cuts

corresponding to production by baryon exchange, and we see no enhancement. Finally we note that we have examined the  $p \pi^+ \pi^+$  mass spectrum at each of our momentum settings separately, and we find no evidence for an enhancement at any of them.

In conclusion, we see no evidence for a narrow ( $\Gamma \leq 60 \text{ MeV}/c^2$ ) resonance in the mass range  $1500 - 2000 \text{ MeV}/c^2$ . The  $40 \mu\text{b}$  production cross section reported by Benvenuti et al. would correspond to a 6 standard deviation enhancement in either of our beam momentum intervals.
