Estradiol (E2) perfusion rapidly increases the strength of fast excitatory transmission and facilitates long-term potentiation in the hippocampus, two effects likely related to its memory-enhancing properties. Past studies showed that E2's facilitation of transmission involves activation of RhoA signaling leading to actin polymerization in dendritic spines. Here we report that brief exposure of adult male hippocampal slices to 1 nM E2 increases the percentage of postsynaptic densities associated with high levels of immunoreactivity for activated forms of the BDNF receptor TrkB and β 1-integrins, two synaptic receptors that engage actin regulatory RhoA signaling. The effects of E2 on baseline synaptic responses were unaffected by pretreatment with the TrkB-Fc scavenger for extracellular BDNF or TrkB antagonism, but were eliminated by neutralizing antisera for β 1-integrins. E2 effects on synaptic responses were also absent in conditional β 1-integrin knockouts, and with inhibition of matrix metalloproteinases, extracellular enzymes that generate integrin ligands. We propose that E2, acting through estrogen receptor- β , transactivates synaptic TrkB and β 1-integrin, and via mechanisms dependent on integrin activation and signaling, reversibly reorganizes the spine cytoskeleton and thereby enhances synaptic responses in adult hippocampus.

INTRODUCTION

Acute treatments with estradiol (E2), the most potent and prevalent estrogen, improve learning in male and female rodents, while reduced levels impair retention in a variety of behavioral paradigms in female rodents (Luine and Frankfurt, 2012). Understanding processes responsible for these effects would be a significant step towards the development of cellular explanations for a broad range of memory-related phenomena. Neurobiological studies have identified two effects of E2 that constitute plausible explanations for its rapid actions on memory and cognition: (1) brief exposures rapidly enhance transmission within cortical networks, and (2) E2 lowers the threshold for inducing long-term potentiation (LTP), a form of plasticity implicated in memory encoding (Bi *et al*, 2000; Foy *et al*, 1999; Kramar *et al*, 2009). How the steroid produces these actions is not yet understood. One possibility is suggested by recent work showing that E2 engages actin-regulatory signaling involved in the production

of LTP (Kramar *et al*, 2009; Yuen *et al*, 2011) and may thereby produce a mild and reversible potentiation of excitatory synaptic responses. Specifically, cytoskeletal effects of E2 are associated with stimulation of RhoA GTPase signaling leading to phosphorylation (inactivation) of the actin-depolymerizing protein cofilin. Moreover, E2-induced increases in the strength of synaptic transmission are accompanied by actin polymerization in dendritic spines and both effects are blocked by latrunculin (Kramar *et al*, 2009), which disrupts actin filament assembly.

The present studies further investigated mechanisms through which E2 influences the spine cytoskeleton. It has been proposed (Spencer *et al*, 2008) that E2 transactivates synaptic TrkB receptors for BDNF. This possibility is of considerable interest here because BDNF engages RhoA-to-cofilin signaling leading to LTP-related actin polymerization (Panja and Bramham, 2014; Rex *et al*, 2009). We first determined if E2 increases TrkB phosphorylation at excitatory synapses in adult rat hippocampus and then asked if scavenging extracellular BDNF blunts the effects of E2 on transmission.

Integrins constitute a second group of receptors that have an essential role in structural changes required for shifting synapses into the potentiated state. Integrins are $\alpha\beta$ heterodimeric transmembrane proteins that mediate cell–extracellular matrix adhesion and exert a strong regulatory influence on the actin cytoskeleton (DeMali *et al*, 2003).

$\beta 1$ Family integrins are localized to excitatory synapse post-synaptic densities (PSDs) (Mortillo *et al*, 2012) and critical for activity-induced synaptic plasticity and the associated actin remodeling (Chan *et al*, 2006; Kramar *et al*, 2006; Nagy *et al*, 2006; Wang *et al*, 2008). Moreover, integrins influence signaling by neighboring receptors including those for estrogen and growth factors (Meng *et al*, 2011; Miranti and Brugge, 2002; Munger and Sheppard, 2011). Accordingly, we tested if in acute hippocampal slices E2 perfusion activates synaptic $\beta 1$ -integrins and if neutralizing $\beta 1$ function reduces the steroid's effect on transmission.

MATERIALS AND METHODS

Hippocampal Slice Electrophysiology

Acute hippocampal slices were prepared from young adult male and female rats (Sprague–Dawley; 40–50 days old) and mice (C57BL6/J; 2.5–3 months), collected into chilled high magnesium artificial cerebral spinal fluid (ACSF) containing (in mM): 124 NaCl, 3 KCl, 1.25 KH_2PO_4 , 5.0 MgSO_4 , 26 NaHCO_3 , and 10 dextrose and then transferred to an interface recording chamber at $31 \pm 1^\circ\text{C}$ with 60–70 ml/h infusion of oxygenated ACSF containing (in mM): 124 NaCl, 3 KCl, 1.25 KH_2PO_4 , 1.5 MgSO_4 , 26 NaHCO_3 , 2.5 CaCl_2 , and 10 dextrose (Trieu *et al*, 2015). Experiments began 1.5–2 h later. To study responses of Schaffer-commissural (S-C) innervation of field CA1b stratum radiatum (SR), stimulating electrodes were placed in CA1a and CA1c SR and a glass recording electrode (2 M NaCl filled, 2–3 M Ω) was positioned in CA1b SR. Stimulation intensity was set to elicit field EPSPs (fEPSPs) that were 50–60% of the maximum spike-free response. fEPSP initial slopes and peak amplitudes were measured using NACGather 2.0 (Theta Burst Corp., Irvine, CA, USA). Baseline stimulation was applied as single pulses at 3/min. LTP was induced with one train of theta burst stimulation (TBS: 10 bursts of 4 pulses at 100 Hz, 200 ms between bursts; at baseline stimulation intensity). For quantitative analyses, the 'N' values reflect the number of slices per group.

Drug Application

Antagonists were introduced to the ACSF perfusion line using a syringe pump; E2 was introduced via the ACSF perfusate at 1.17 baseline rate. Vehicle controls and antagonists were run in parallel using slices from the same animal. Drug, neutralizing antisera, and TrkB-Fc experiments used concentrations selected from the literature and our prior work. Agents used included estrogen receptor- α (ER α) antagonist MPP (1, 3-Bis (4-hydroxyphenyl)-4-methyl-5-[4-(2-piperidinylethoxy) phenol]-1H-pyrazole dihydrochloride), ER β antagonist PHTPP (4-[2-phenyl-5,7-bis(trifluoromethyl)pyrazolo[1,5-a]pyrimidin-3-yl]phenol), β -E2 ((17 β)-estra-1,3,5 (10)-triene-3,17-diol), GM6001 and batimastat (Tocris, Bristol, UK), and G-15 (Chemical, Ann Arbor, MI); these compounds were prepared in 100% dimethylsulfoxide and diluted to a final concentration in ACSF. TrkB-Fc Chimera Protein (688-TK; R&D Systems, Minneapolis, MN), ANA-12 (Tocris), and neutralizing anti- $\beta 1$ -integrin (MAB1987Z; Millipore, Billerica, MA) were diluted in ACSF to 2 $\mu\text{g}/\text{ml}$, 500 nM, and 0.2 mg/ml, respectively. The latter two reagents

were applied locally by pressure ejection (Picospritzer; General Valve, Fairfield, NJ) (Kramar *et al*, 2006).

Immunostaining and Fluorescence Deconvolution Tomography

Hippocampal slices were processed for dual immunofluorescence and fluorescence deconvolution tomography as described (Seese *et al*, 2012, 2013). Primary antisera cocktails included rabbit anti-ER α (1:700, sc-543), mouse anti-ER β (1:700, sc-390243) (Santa Cruz Biotechnology, Santa Cruz, CA), rabbit anti-pTrkB Tyr515 (1:500, NB100-92656; Novus Biochem, Littleton, CO) (Simmons *et al*, 2013) and anti-activated $\beta 1$ -integrin (1:400, MAB2259Z, Millipore, Middleton MA) (Ni *et al*, 1998) in combination with anti-PSD95 (1:1000, MA1-045 (Thermo Scientific, Waltham, MA) or ab12093 (Abcam, Cambridge UK)). Secondary antisera included AlexaFluor 594 anti-rabbit IgG and AlexaFluor 488 anti-mouse IgG (1:1000; Life Technologies, Carlsbad, CA). Epifluorescence image z-stacks were collected at $\times 63$ in 200 nm steps through 2 μm from CA1b SR (4–5 stacks per slice). Images were processed through restorative deconvolution (99% confidence, Volocity 4.0; Perkin-Elmer) and individual z-stacks were used to construct a three-dimensional (3D) montage of each sample field ($136 \times 105 \times 2 \mu\text{m}^3$); elements meeting size constraints of synapses, and detected across multiple intensity thresholds, were quantified using automated systems (Rex *et al*, 2009; Seese *et al*, 2013). This resulted in the analysis of $\sim 30\,000$ PSDs per sample field and $> 100\,000$ PSDs per slice. Elements were considered double labeled if there was overlap in the two fluorophores as assessed in 3D. The density of a particular immunolabel colocalized with PSD95 was measured for each synapse and expressed as a percent of all double-labeled PSDs for construction of intensity frequency distributions.

$\beta 1$ -Integrin Knockouts

Conditional $\beta 1$ -integrin knockouts (cKOs) were created by crossing mice with floxed $\beta 1$ -integrin gene exon 3, with mice expressing Cre-recombinase under the CaMKII promoter (Chan *et al*, 2006; Mortillo *et al*, 2012). In progeny, Cre expression in excitatory hippocampal and cortical neurons (Tsien *et al*, 1996) leads to excision of $\beta 1$ exon 3, and disrupted $\beta 1$ protein expression, from ~ 3 weeks of age; experiments were conducted on 2–3-month-old mice. The genetic manipulation was verified by PCR of genomic DNA and by rtPCR of mRNA, isolated from hippocampus, using primers spanning $\beta 1$ exon 3: 5'-GAATTTGCAACTGGTTTCTGG-3' and 5'-ACAACAGCTGCTTCTAAAATTGA-3'. Mice were verified to contain Lox-p sites and Cre-recombinase expression by PCR of DNA from tail snips.

Statistics

Results are presented as means \pm SEM. Statistical significance ($p < 0.05$) was evaluated using two-tailed Student's *t*-test, and one- and two-way analysis of variance (GraphPad Prism, San Diego, CA). In graphs asterisks denote the level of significance (* $p < 0.05$, ** $p < 0.01$, and *** $p < 0.001$).

RESULTS

Synaptic Localization of ER α and ER β

Both ER α and ER β have been localized to dendritic spines (Hara et al, 2015). We used dual fluorescence deconvolution tomography (FDT) (Figure 1a) (Seese et al, 2012, 2013) to compare the distribution and density of these receptors at excitatory synapses in CA1 SR in hippocampal slices from young adult male rats. While absolute values for labeling intensity cannot be compared for two antibodies, intensity–frequency–distribution curves (% double-labeled synapse-sized elements across a series of immunolabeling-density bins) provide a relative measure (normalized per slice) for comparison of ER α and ER β . The incidence of PSD

localization and intensity–frequency–distribution curves were comparable for the two ERs ($p > 0.70$; Figure 1b), suggesting that there were no differences in their relative abundance at field CA1 SR synapses.

Exogenous E2 Enhances Transmission via ER β

Next, we tested which ER mediates the synaptic response facilitation produced by exogenous E2. E2 (1 nM) was perfused for 20 min into hippocampal slices from young adult male rats with low-frequency (3/min) stimulation applied to the S-C projections; fEPSPs were collected from CA1b SR. Response size increased within 2–5 min of E2 arrival in the chamber and shortly thereafter reached a

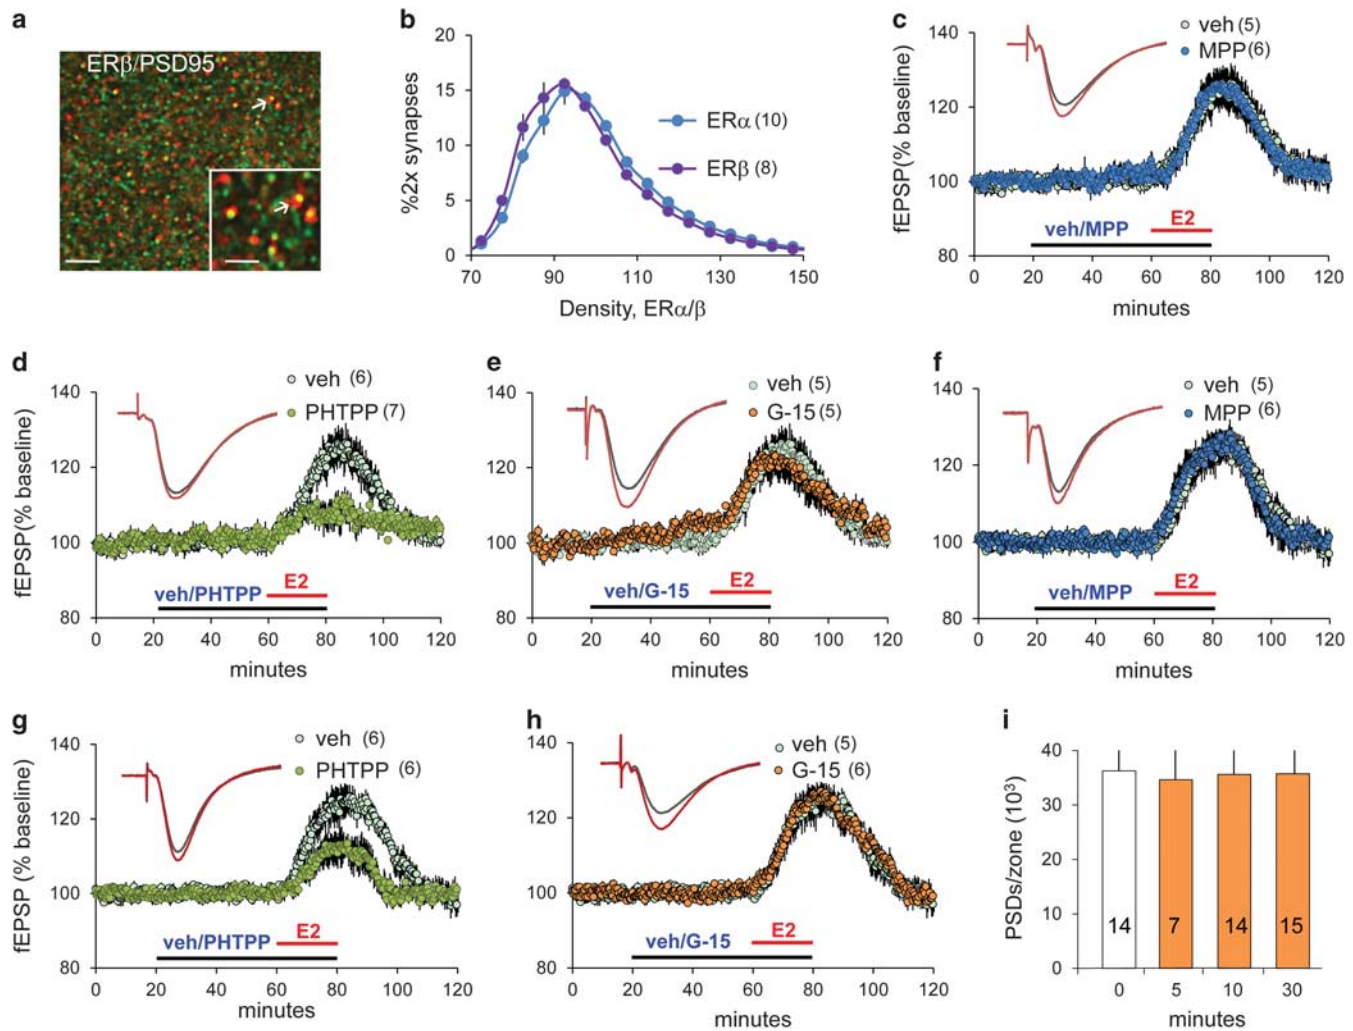

Figure 1 Estradiol (E2) enhances synaptic transmission through estrogen receptor- β (ER β) in rat slices. (a) Deconvolved image shows postsynaptic density 95 (PSD95) (green) and ER β (red) immunostaining; double-labeled elements appear yellow (arrows; bar: 10 μ m; inset bar: 1 μ m). (b) Immunolabeling intensity frequency distributions for ER α and ER β colocalized with PSD95 (% of all double-labeled (2 \times) PSD95+ elements shown; mean \pm SEM values; $F_{(19,320)} = 11.29$, $p > 0.70$, two-way analysis of variance (ANOVA)). (c–e) E2 (1 nM) applied to male slices for 20 min rapidly increased excitatory postsynaptic potential (fEPSP) slope; this response was not affected by pretreatment with (c) ER α antagonist MPP (1, 3-bis (4-hydroxyphenyl)-4-methyl-5-[4-(2-piperidinyloxy) phenyl]-1H-pyrazole dihydrochloride) (3 μ M) or (e) GPER1 antagonist G-15 (100 nM) but was blocked by (d) ER β antagonist PHTPP (3 μ M; $t_{(10)} = 3.658$, $p = 0.005$ for E2 vs E2+PHTPP; two-tailed t-test). (f–h) E2 (1 nM) applied to female slices for 20 min enhanced fEPSPs as in males; antagonists of ER α (f) or GPER1 (h), perfused at the same concentrations used in the male studies, had no effect on E2's response facilitation. (g) However, ER β antagonist PHTPP markedly reduced effects of E2 ($t_{(10)} = 2.69$, $p = 0.027$; two-tailed t-test). (i) Numbers of PSD95+ synapses do not differ with time after E2 perfusion onset in male slices ($F_{(3,46)} = 0.268$, $p = 0.848$, one-way ANOVA). Numbers within parentheses and on bars denote the number of slices per group.

plateau at 15–30% above baseline (Figure 1c). Past work showed that E2's effects on fEPSPs in field CA1 are not accompanied by changes in S–C paired-pulse facilitation or NMDA receptor currents, measures that would reflect changes in neurotransmitter release (Kramar *et al*, 2009). Moreover, feedforward inhibition mediated by GABA-A or GABA-B receptors was not detectably affected by 20 min E2 perfusion (Kramar *et al*, 2009).

The response enhancement produced by E2 was not affected by ER α antagonist MPP (3 μ M; E2: 23.97 \pm 9.47%, E2+MPP: 25.12 \pm 11.13%) but was effectively eliminated by ER β blocker PHTPP (3 μ M; E2: 22.25 \pm 7.47%, E2+PHTPP: 6.25 \pm 7.16%, p = 0.005; E2+PHTPP vs baseline, p = 0.07) (Figures 1c and d). These results accord with evidence that ER β agonist WAY-200070 replicates the effects of E2 on transmission, whereas ER α agonist PTT does not (Kramar *et al*, 2009). The G-protein-coupled ER-1 (GPER1) reportedly contributes importantly to exogenous E2 effects on excitatory transmission in female rodents (Kumar *et al*, 2015; Oberlander and Woolley, 2016). However, in slices from male rats GPER1 antagonist G-15 (100 nM) did not attenuate E2's effects on S-C fEPSPs (E2: 24.34 \pm 6.19%, E2+G-15: 22.60 \pm 2.57%; Figure 1e). These results indicate that in males ER β mediates effects of applied E2 on S-C response facilitation.

Similar results were obtained using slices from female rats: E2 increased fEPSPs in vehicle-treated slices with the same magnitude and time course as in male slices, and these effects did not differ across estrus cycle stages (diestrus: 44% of cases; estrus: 26%; proestrus: 26%). Pretreatment with ER β blocker PHTPP markedly reduced but, in contrast to effects in males, did not eliminate response enhancement by E2 (E2: 25.1 \pm 10.55%, E2+PHTPP: 13.37 \pm 8.52%; p = 0.027; E2+PHTPP vs baseline, p = 0.004; Figure 1g), whereas ER α and GPER1 antagonists had no effect (E2: 24.95 \pm 8.67% vs E2+MPP: 26.27 \pm 5.24%; E2: 26.54 \pm 11.09% vs E2+G-15: 26.34 \pm 5.20%; Figures 1f and h).

Many studies have shown that E2 increases the number of spines (Hara *et al*, 2015; Luine and Frankfurt, 2012; Mukai *et al*, 2007) and spine synapses (Fester and Rune, 2015; Leranth *et al*, 2000), but whether this effect occurs quickly enough to contribute to the rapid facilitation of synaptic responses is unclear. Accordingly, we used FDT to count the number of PSD95-immunopositive (+) synapses in CA1 SR of slices harvested 5–30 min after E2 perfusion onset: the steroid did not increase the number of immunolabeled PSDs through 30 min (Figure 1i).

E2 Activates Synaptic TrkB and β 1-Integrins

E2 initiates RhoA signaling leading to cofilin phosphorylation and actin polymerization in dendritic spines; this sequence is critical for response facilitation by the steroid (Kramar *et al*, 2009). Synaptic TrkB (Rex *et al*, 2007) and β 1-integrins (Kramar *et al*, 2006) both promote the dendritic spine actin filament assembly that is essential for TBS-induced LTP. This raises the possibility that E2 produces its effects on actin, and thus on synaptic facilitation, by engaging one or both of these receptors.

We tested for TrkB activation in male rat slices using dual immunofluorescence and FDT to measure immunoreactivity (ir) for phosphorylated (p) TrkB Tyr515 (Chen *et al*, 2010)

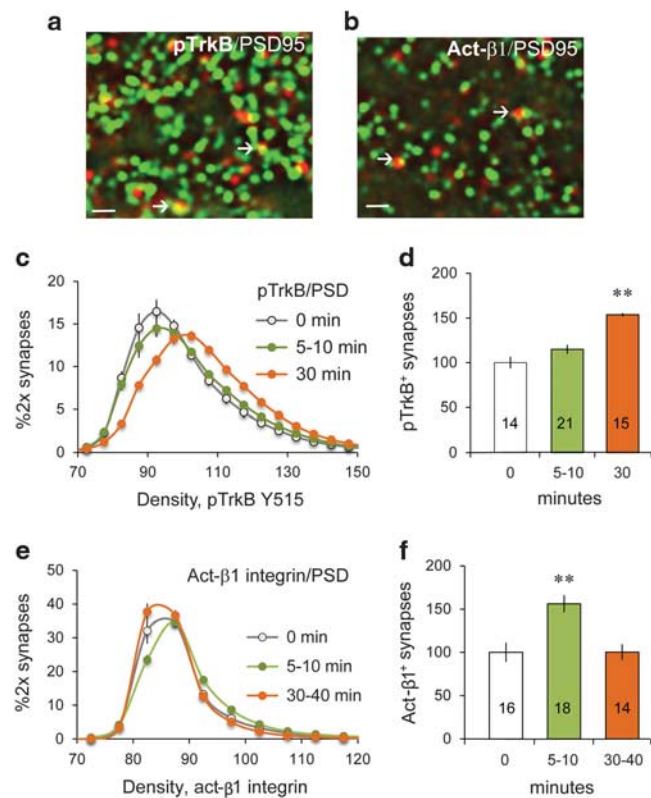

Figure 2 Estradiol (E2) perfusion activates synaptic TrkB and β 1-integrin. (a and b) Images show dual immunolabeling for (a) postsynaptic density 95 (PSD95) (green) and pTrkB Y515 (red) and (b) for PSD95 (green) and activated β 1 (red) (bar: 1.5 μ m); double-labeled elements appear yellow (arrows). (c) Intensity frequency distributions for pTrkB-ir colocalized with PSD95 in slices collected before (0 min), 5–10 min, or 30 min after E2 perfusion onset (means \pm SEM); the 30 min curve was statistically different from 0 min baseline ($F_{(56,1363)} = 9.82$, $p < 0.0001$, two-way analysis of variance (ANOVA)). (d) Plot of the percent of pTrkB+ PSDs with high density (≥ 110) pTrkB-ir normalized to the 0 min group mean shows an increase in densely pTrkB+ PSDs at 30 min only ($F_{(2,49)} = 7.30$; $p < 0.002$, one-way ANOVA; $**p < 0.01$, 30 vs 0 min). (e) Intensity frequency distributions for activated β 1-ir plotted as in (c) (SEM bars smaller than icons); The 5–10 min curve was right-shifted relative to 0 min ($F_{(56,1463)} = 3.87$, $p < 0.0001$, two-way ANOVA). (f) Percent of activated β 1+ PSDs, normalized to '0 min' mean, shows an increase at 5–10 min ($F_{(2,43)} = 11.81$, $p < 0.0001$, one-way ANOVA; $**p < 0.01$, 5 vs 0 min). Numbers in bars denote the number of slices per group.

colocalized with PSD95 (Figure 2a). E2 perfusion caused a rightward shift in the intensity–frequency–distribution for pTrkB+ elements that was modest after 5–10 min but robust after 30 min relative to vehicle control (0 min) slices ($p < 0.0001$), indicating that E2 increased pTrkB levels in the postsynaptic compartment (Figure 2c). As a consequence, the percentage of double-labeled contacts highly enriched in pTrkB (immunolabeling intensities > 110) was significantly elevated at 30 min (Figure 2d).

We used the same experimental design to test if E2 increases the proportion of excitatory synapses associated with activated β 1-integrin (Figure 2b). E2 perfusion caused a pronounced rightward shift in the intensity–frequency–distribution for activated β 1 colocalized with PSD95; the effect was robust at 5–10 min ($p < 0.0001$) and greatly reduced by 30 min (Figure 2e). The percentage of PSDs

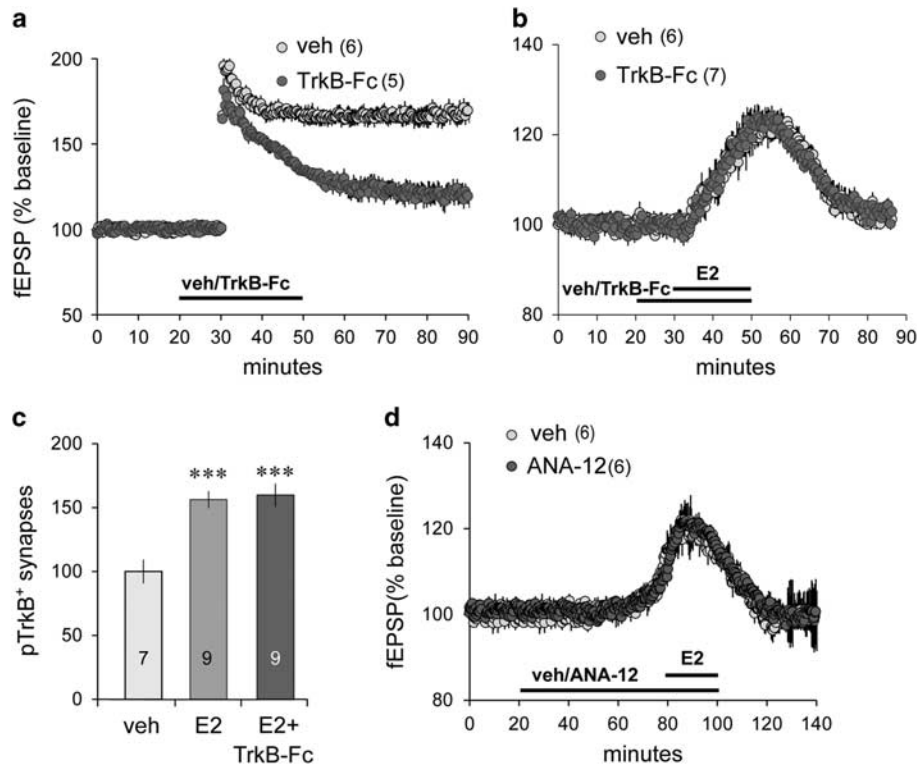

Figure 3 Estradiol (E2) effects on transmission do not depend on brain-derived neurotrophic factor (BDNF) or TrkB signaling. (a) TrkB-Fc (2 μ g/ml; at horizontal bar) blocked Schaffer-commissural (S-C) long-term potentiation (LTP) induced with theta burst stimulation (TBS) applied at 30 min ($t_{(12)} = 3.83$, $p = 0.002$ vs veh at 55–60 min post-TBS; two-tailed t -test). (b) TrkB-Fc did not influence E2's effects on synaptic responses ($t_{(9)} = 0.510$, $p = 0.623$ vs veh; two-tailed t -test). (c) The percentage of postsynaptic density 95-positive (PSD95+) elements colocalized with dense pTrkB-ir was similarly elevated in slices treated with E2 or E2+TrkB-Fc, relative to vehicle (veh) control values ($F_{(2,22)} = 12.4$, $p = 0.0002$, one-way analysis of variance (ANOVA); *** $p < 0.001$ vs veh; Bonferroni's *post hoc* test). (d) ANA-12 (750 nM) did not block E2's effects on transmission ($t_{(10)} = 0.25$, $p = 0.81$ vs veh; two-tailed t -test). Numbers within parentheses and on bars denote the number of slices per group. A full color version of this figure is available at the *Neuropsychopharmacology* journal online.

associated with dense activated $\beta 1$ immunolabeling was also elevated at 5–10 min but not 30 min time points (Figure 2f).

Effects of Sequestering BDNF or Blocking TrkB on E2-Induced Synaptic Facilitation

Next, we tested if BDNF is required for E2-driven TrkB activation and synaptic response facilitation in slices from male rats. TrkB-Fc scavenges extracellular BDNF (Shelton *et al*, 1995) and blocks TrkB activation in many experimental systems. It also prevents stable TBS-LTP (Rex *et al*, 2007). TrkB-Fc (2 μ g/ml) pretreatment produced the predicted elimination of LTP (Figure 3a) but did not block E2's facilitation of transmission: The S-C fEPSP response facilitation after 30 min E2 perfusion was the same with and without TrkB-Fc present (veh: $+20.0 \pm 1.59\%$; TrkB-Fc: $+22.20 \pm 3.87\%$) (Figure 3b). Moreover, E2-induced increases in postsynaptic pTrkB-ir were unaffected by TrkB-Fc (Figure 3c). These results indicate that E2's effects on synaptic TrkB constitute transactivation rather than changes in ligand action.

We tested if E2 effects on synaptic responses require TrkB activity. ANA-12 is a high-affinity TrkB antagonist shown to reduce BDNF-induced growth effects (Cazorla *et al*, 2011) and TrkB phosphorylation (M Chao, personal communication). At 500 nM ANA-12 disrupts field CA1 LTP in male

slices (not shown). Here we used a higher concentration (750 nM) for 60 min before and during E2 treatment; ANA-12 did not diminish E2's enhancement of synaptic responses (E2: $19.76 \pm 3.49\%$; E2+ANA-12: $20.18 \pm 2.20\%$) (Figure 3d).

E2-Induced Synaptic Facilitation Depends Upon $\beta 1$ -Integrin Function

In contrast to effects of TrkB manipulation, perfusion of function blocking antisera for $\beta 1$ -integrin (Kramar *et al*, 2006) fully disrupted E2's enhancement of S-C responses, without altering baseline transmission (Figure 4a): the fEPSP slope in anti- $\beta 1$ -treated slices was $97.0 \pm 0.8\%$ of pretreatment baseline just before E2 perfusion and $96.1 \pm 0.4\%$ at its conclusion. This indicates that $\beta 1$ -integrin function is essential for E2-induced increases in fEPSPs. To further test this conclusion, we evaluated the effects of E2 perfusion in hippocampal slices from cKO mice in which hippocampal $\beta 1$ expression is knocked down in CaMKII-expressing, excitatory neurons beginning at ~ 3 weeks of age; expression is retained in glia and GABAergic neurons (Chan *et al*, 2006). PCR analysis of genomic DNA (Figure 4b) and reverse-transcribed DNA purified from the hippocampus (not shown) verified the excision of $\beta 1$ exon 3 and the presence of truncated mRNA transcripts in cKOs relative to floxed $\beta 1$ wild types (WTs; lacking Cre-recombinase expression).

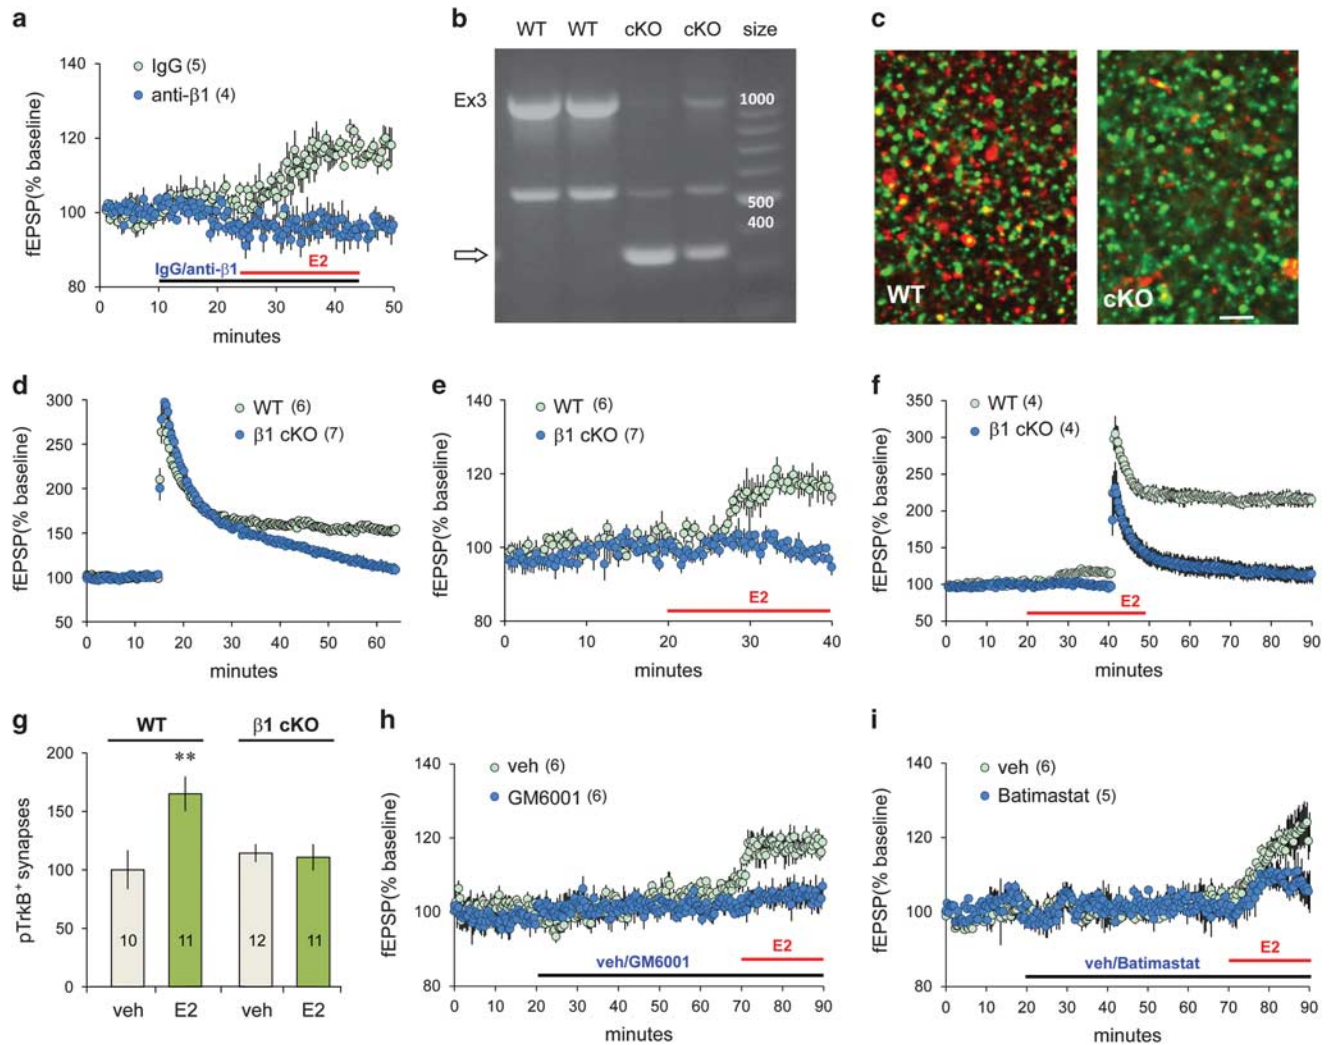

Figure 4 Estradiol's (E2's) effects on synaptic transmission depend upon $\beta 1$ -integrin function. (a) Plot of field CA1 excitatory postsynaptic potentials (fEPSPs) shows that neutralizing anti- $\beta 1$ blocked E2's enhancement of Schaffer-commissural (S-C) transmission ($t_{(16)} = 2.78$, $p = 0.013$; two-tailed t -test for increase above baseline at 20 min post-E2 onset), whereas control immunoglobulin G (IgG) was without effect. (b) PCR products from hippocampal genomic DNA, for samples from homozygous floxed $\beta 1$ wild types 'WTs' (lacking Cre expression), and homozygous conditional $\beta 1$ -integrin knockout (cKO) mice, generated using primers that span $\beta 1$ exon 3 (base pair size markers at right): WTs have a prominent ~ 1000 bp band reflecting the presence of the floxed $\beta 1$ exon 3 (Ex 3; verified by sequencing), whereas the cKOs have a weak band at this position but a prominent band at 300 bp (arrow) corresponding to the recombined sequence generated with $\beta 1$ exon 3 excised (Chan *et al*, 2006). (c) Deconvolved images of immunolabeling for postsynaptic density 95 (PSD95) (green) and $\beta 1$ -integrin (red) in CA1 SR show the marked reduction in punctate $\beta 1$ -ir in a cKO mouse relative to a paired floxed $\beta 1$ WT; retention of some $\beta 1$ -ir is consistent with continued expression by glia and inhibitory neurons (bars = 3 μm). (d) Theta burst stimulation (TBS)-induced long-term potentiation (LTP) was severely impaired in $\beta 1$ -integrin cKOs ($t_{(11)} = 4.03$, $p = 0.002$ vs WT; two-tailed t -test). (e) E2 did not increase baseline transmission in $\beta 1$ cKOs, although increases were robust in WTs ($t_{(6)} = 5.05$, $p = 0.002$; two-tailed t -test at 20 min post-E2 onset). (f) In the same slices shown in (e), TBS-induced LTP was enhanced in E2-treated WT slices ($110.9 \pm 5.43\%$ over E2 baseline; ~ 2 -fold normal, WT LTP effect) but was absent in E2-treated slices from $\beta 1$ cKOs. (g) Fluorescence deconvolution tomography (FDT) quantification of densely pTrkB Y515-immunoreactive PSDs (immunolabeled for PSD95) shows an increase in pTrkB+ synapses with E2 vs vehicle (veh) treatment in field CA1 SR of floxed $\beta 1$ WTs but not $\beta 1$ cKOs ($F_{(1,40)} = 7.23$, $p = 0.0104$, two-way analysis of variance (ANOVA); ** $p < 0.01$ for veh- vs E2-treated WT; $p > 0.05$ for veh- vs E2-treated $\beta 1$ cKOs; Bonferroni *post hoc* test). (h and i) Effects of E2 on baseline transmission were (h) absent in slices pretreated with the matrix metalloproteinase (MMP) inhibitor GM6001 (25 μM) ($t_{(10)} = 3.67$, $p = 0.004$; two-tailed t -test for E2 vs E2+GM6001 1% increase above baseline), and (i) reduced by MMP inhibitor batimastat (4 nM) ($t_{(10)} = 4.27$, $p = 0.034$; two-tailed t -test for % increase above baseline).

Moreover, punctate $\beta 1$ -ir was markedly reduced in CA1 SR of cKOs relative to WTs (Figure 4c). Previous studies showed that LTP consolidation is blocked in $\beta 1$ cKOs (Chan *et al*, 2006). We confirmed this result (Figure 4d) and then tested effects of E2 perfusion. E2 had no significant effect on synaptic responses in slices from $\beta 1$ cKOs (Figure 4e), supporting the conclusion that $\beta 1$ -integrin function is essential for E2's actions on synaptic transmission. Moreover, application of TBS to E2-treated slices produced a

markedly greater than normal LTP in WTs, as described previously (Bi *et al*, 2000; Foy *et al*, 1999), but failed to induce potentiation in $\beta 1$ cKOs. (Figure 4f). Estrogen reduces feedback inhibition in the hippocampus (Steffensen *et al*, 2006), an effect that could potentially enhance LTP induction. However, applied E2 does not influence burst response facilitation during S-C TBS (Kramar *et al*, 2009); this indicates it acts primarily on events that follow initial induction at excitatory synapses.

Next, we asked if TrkB activation by perfused E2 is dependent on $\beta 1$ -integrins. Slices from $\beta 1$ cKOs and floxed $\beta 1$ WT mice were treated with E2 for 30 min and then processed for dual immunofluorescence and FDT (as above). The increase in the proportion of PSDs associated with dense pTrkB-ir after E2 treatment was confirmed for WT mice ($p < 0.001$) but absent for $\beta 1$ cKOs (Figure 4g). These results constitute the first evidence that integrins influence activation of synaptic TrkB.

Prior studies have shown that $\beta 1$ -integrin-dependent LTP is blocked by inhibitors of matrix metalloproteinase 9 (MMP9) (Nagy *et al*, 2006; Wang *et al*, 2008), which cleaves matrix proteins to generate integrin ligands, and that E2 can increase extracellular MMP9 activity (Merlo and Sortino, 2012). We tested if MMP inhibition alters E2 actions on synaptic responses in slices from male rats. Perfusion of the broad-spectrum MMP inhibitor GM6001 (25 μ M) blocked E2's facilitation of S-C fEPSPs ($p = 0.004$) (Figure 4h). Perfusion of batimastat (4 nM), an inhibitor with greater selectivity for MMP2 and MMP9, significantly attenuated E2's response facilitation ($p = 0.034$; Figure 4i). These results indicate that E2's activation of $\beta 1$ is dependent on the generation of extracellular integrin ligands.

DISCUSSION

We previously hypothesized that E2 perfusion generates a weak and unstable form of LTP (Kramar *et al*, 2009). Evidence for this came from the observation that E2 activates elements of actin signaling required for potentiation and that inhibiting this signaling eliminates E2's effects on synaptic responses. However, the hypothesis lacked information on how E2, presumably acting on membrane ERs, engages postsynaptic cytoskeletal signaling. One possibility is that ER β , shown here and previously (Kramar *et al*, 2009; Smejkalova and Woolley, 2010) to mediate response facilitation, acts through G proteins to directly activate Rho GTPases leading to cofilin phosphorylation and actin filament assembly. An alternative explanation is that bound ERs act indirectly by stimulating other synaptic components that drive dendritic spine actin polymerization; we tested this point with regard to integrins and TrkB, previously shown to be critical for activity-regulated actin polymerization in field CA1 (Kramar *et al*, 2006; Rex *et al*, 2007).

We confirmed that ER α and ER β are comparably abundant at PSDs in CA1 SR and, using receptor-specific antagonists, obtained evidence that ER β mediates exogenous E2's synaptic response facilitation in slices from male rats. These results agree with reports that ER β mediates postsynaptic actions of applied E2 in male CA1 (Kramar *et al*, 2009; Oberlander and Woolley, 2016). In contrast, ER β antagonist PHTPP did not fully block E2's synaptic response facilitation in slices from female rats even though ER α and GPER1 antagonists were without effect. The latter result was surprising given evidence from studies using receptor agonists that ER β is involved but GPER1 has a larger role in postsynaptic S-C response facilitation with E2 infusion in female rats (Kumar *et al*, 2015; Oberlander and Woolley, 2016). Clearly, more work is needed to understand the apparent discrepancies between these studies and sex differences in GPER1 regulation of synaptic transmission (Kumar *et al*, 2015). Although the present results imply that

ER α does not mediate acute effects of exogenous E2 on synaptic physiology in either sex, our experiments did not specifically explore presynaptic actions of this receptor (Oberlander and Woolley, 2016) or possibilities that ER α may become involved when E2 is applied for longer intervals or at higher concentrations. The last point is important given the possibility that locally derived E2 can reach higher concentrations in the confined space of the synaptic junction (Ooishi *et al*, 2012).

Applied E2 increased the levels of activated (Y515-phosphorylated) TrkB at PSD95+ excitatory synapses within 30 min. This increase was not attenuated in the presence of BDNF scavenger TrkB-Fc, indicating that E2 signaling transactivates the BDNF receptor. Transactivation of TrkB, in the absence of BDNF, has been described for several treatments including 5-HT (Samarajeewa *et al*, 2014), epidermal growth factor (Puehringer *et al*, 2013), antidepressant drugs (Rantamaki *et al*, 2011), and adenosine (Rajagopal and Chao, 2006). Mechanisms are not fully resolved but links between G-protein-coupled receptors (GPCRs) and Src kinases are well established (Rajagopal and Chao, 2006). This is noteworthy because ERs signal through Src kinases (Bi *et al*, 2000) and Src inhibitors block TrkB phosphorylation associated with LTP (Chen *et al*, 2010). We therefore suggest that ER β signaling through a Src kinase may mediate effects of E2 on TrkB.

The functional consequences of E2-induced TrkB transactivation are unclear: this response appears to be too slow to initiate the rapid effects of E2 on synaptic responses (within 5 min), although TrkB signaling may contribute to the maintenance of enhanced responses. It is interesting in this regard that TrkB-Fc does not affect the first few minutes of LTP but causes potentiation to decay thereafter. Moreover, we found the TrkB antagonist ANA-12, applied at concentrations that block TBS-induced LTP, did not attenuate E2's effects on S-C synaptic responses. This indicates that TrkB does not mediate the rapid effects of applied E2 on synaptic physiology. Another possibility is that E2's activation of TrkB contributes to the later production of new dendritic spines. We did not detect increases in PSDs after 30-min E2 perfusions, although initial spine changes may be evident at this time point. Further work is needed to determine if E2's transactivation of TrkB contributes to changes in spine and synapse numbers.

E2 caused synaptic $\beta 1$ -integrins to shift into their activated state and work with neutralizing antisera, and $\beta 1$ -integrin cKO mice showed that this effect is critical for exogenous E2's enhancement of S-C synaptic responses. Effects of E2 on synaptic integrins were rapid and brief: activated $\beta 1$ levels were increased within 5–10 min but had subsided 25 min later. A similarly rapid and transient activation of synaptic $\beta 1$ -integrins was found in LTP experiments with activation peaking at 2 min post-TBS and dissipating within 10 min (Babayán *et al*, 2012).

Integrin transactivation occurs in a broad range of contexts and cell types, and is argued to be involved in clinically important conditions such as atherosclerosis and cancer. For example, the inflammatory mediator leukotriene B4 acting through a defined membrane receptor transactivates integrins leading to signaling through integrin-associated focal adhesion kinase and actin polymerization (Moraes *et al*, 2010). These events are present within 15 min

and thus bear some resemblance to synaptic effects of perfused E2. A recent and detailed description of integrin transactivation by GPCRs concluded that two mechanisms are involved: (i) stimulation of the small GTPase Rap1 and actions on submembrane proteins (kindlins) that promote integrin activation, and (ii) recruitment of adaptor proteins to the C terminus of the β -integrin subunit (Ortega-Carrion *et al*, 2015). The present studies also provide evidence that β 1-integrins are necessary for E2's activation of TrkB. This was not entirely unexpected given that integrins interact with other transmembrane proteins, including growth factor receptors, in many circumstances (Meng *et al*, 2011; Munger and Sheppard, 2011). However, synaptic TrkB activation could also be secondary to rapid cytoskeletal changes that accompany integrin activation, events that may influence the status of various membrane receptors. It is also possible that the enhanced synaptic responses elicited by E2, which require functional β 1-integrins, produce effects that alter the status of synaptic TrkB. Resolving these questions will be a challenging but necessary step in explicating E2's actions on excitatory transmission.

Further work showed that MMP inhibition blocks the effects of E2 on synaptic physiology. These extracellular enzymes both generate integrin ligands from the extracellular matrix and process proBDNF to produce the mature neurotrophin (Ethell and Ethell, 2007). However, given evidence that neither BDNF sequestration with TrkB-Fc nor TrkB antagonism disrupts E2's facilitation of synaptic responses, the MMPs most likely contribute to E2's effects on transmission by enabling integrin activities. It is possible that constitutive MMP activity is required to maintain an integrin ligand pool. Alternatively, perfused E2 may activate MMPs, as previously reported for neuroblastoma (Merlo and Sortino, 2012), which then produce integrin ligands. Past work showed that induction of field CA1 LTP activates MMP9, and that blocking the proteinase disrupts potentiation (Nagy *et al*, 2006; Wang *et al*, 2008). Moreover, perfusion of activated MMP9 initiates β 1-integrin-mediated signaling to cofilin, actin polymerization, and potentiation of synaptic responses. Related to this, LTP stabilization is prevented by intracellular application of agents that block exocytosis (Wang *et al*, 2008). Tissue plasminogen activator (tPA) is one candidate for the releasable intermediary: E2 stimulates tPA secretion (Hoetzer *et al*, 2003) and, via generation of extracellular plasmin, it activates MMPs (Tsilibary *et al*, 2014). As inhibitors of tPA block LTP (Hoffman *et al*, 1998), it should be straightforward to test if they similarly block E2-induced increases in fast, excitatory synaptic transmission.

The above arguments can be summarized in a simplified, provisional model of how E2 enhances EPSPs and primes synapses for LTP (Figure 5). Importantly, this scheme does not specifically address E2's actions on transmission in females, where the situation is likely more complicated than in males. E2 is synthesized within axon terminals and in hippocampal field CA1 locally produced E2 is required for LTP in females only (Vierk *et al*, 2012). There is also evidence from whole-cell recordings that exogenous E2 has synapse-specific effects on pre- vs postsynaptic mechanisms that differ between males and females (Oberlander and Woolley, 2016). Information on whether transactivation events shown here to mediate the effects of exogenous E2 in males are also engaged by agonists for the different ERs, and

Figure 5 Proposed mechanisms whereby exogenous estradiol (E2) enhances fast excitatory transmission in adult male hippocampus. (a) Rapid E2 effects involving β 1-integrins. Published work indicates that perfused E2 acting through synaptic estrogen receptor- β (ER β) engages Src family kinases and Ras/Rap GTPases, and releases factors (eg, tPA: ?) that activate extracellular matrix metalloproteinases (MMPs); together, these intra- and extracellular events shift synaptic β 1-integrins into their activated configuration. Integrins then drive downstream small Rho GTPases that enable local polymerization of filamentous actin (F-actin) from actin monomers (G-actin); this cytoskeletal reorganization affects AMPA receptors (AMPA-Rs) so as to increase the effects of released glutamate, resulting in enhanced synaptic currents. (b) Delayed activation of TrkB. Integrin signaling set in motion by E2/ER β could affect TrkB through three routes: a. transactivation resulting from β 1-dependent stimulation of small GTPases; b. formation and elaboration of actin networks that affect the probability of TrkB phosphorylation; and c. enhanced depolarization produced by afferent activity, an effect dependent on β 1-integrin activation. Earlier work showing that actin polymerization is critical for E2's enhancement of synaptic transmission favors hypothesis 'b'. A full color version of this figure is available at the *Neuropsychopharmacology* journal online.

by locally derived E2 most particularly in females, should provide better understanding of synapse- and region-specific E2 actions (Briz *et al*, 2015; Oberlander and Woolley, 2016) and the larger question of sex differences in learning-related synaptic plasticity.

FUNDING AND DISCLOSURE

The authors declare that this work was funded by NINDS grants NS045260, NS085709 and T32 NS45540 (the latter supported SK) and by funds from the Thompson Foundation to the UCI Center for Autism Research and Translation. The authors declare no conflict of interest.

ACKNOWLEDGMENTS

We thank Dr Ivan Soltesz for providing CaMKII-Cre mice used for generating the $\beta 1$ cKOs, Dr Moses Chao for information on TrkB antagonists, and Dr Julie Lauterborn for comments on the manuscript.
