## RISK ASSESSMENT OF INHALED PARTICLES INTEGRATING TIME-ACTIVITY PATTERNS WITH RESPIRATORY TRACT PARTICLE DEPOSITION MODELS\*

G. M. SCHUM, R. F. PHALEN and M. J. OLDSHAM

California Department of Toxic Substances Control, P.O. Box 806, Sacramento, CA 95812-0806, U.S.A.

**Abstract**—Human daily activity patterns and age-scaled anatomical models are used to calculate expected daily particle deposition rates for adults and children. Daily doses in  $\mu\text{g kg}^{-1}$  per day per  $\mu\text{g m}^{-3}$  of air of particles in various sizes are calculated for the N-P, T-B and P regions of adults that work indoors at a low level of exertion or that work more heavily outdoors and for active children. Higher doses are seen for higher levels of activity, as expected. Whether or not children's doses are larger than those of adults depends on particle size and region of the respiratory tract considered.

### INTRODUCTION

EVALUATING the risks associated with chronic exposure to aerosol particles requires a quantitative estimate of the actual mass depositing in the respiratory tract. Mathematical models available to predict particle deposition in the major regions of the respiratory tract generally predict deposition of particles of known size at specific ventilation rates. Risk assessments, however, generally involve making simplifying assumptions about 'typical' particle sizes and 'average' ventilation rates (e.g. breathing particles less than  $10 \mu\text{m}$  at a  $20 \text{ m}^3 \text{ day}^{-1}$  ventilation rate). However, particle deposition in the respiratory tract changes dramatically with particle size at different ventilation rates. Our research involves including realistic activity patterns and particle sizes in aerosol deposition predictions.

### METHODS AND RESULTS

Recently-available studies of human daily activity patterns which provide estimates of the fraction of time U.S. subpopulations spend in activities with different ventilation rates were used to estimate daily time-activity distributions. Activity-specific ventilation rates throughout a typical day for persons aged 6 and 18 years were then used as input to aerosol deposition models (U.S. EPA, 1985). Ventilation rates are shown in Table 1.

The anatomical models were developed from the tracheobronchial data of PHALEN *et al.* (1985). The bronchial airways were scaled to a dead space volume based on height and the diameters were then increased by 20% to correspond to volumes at total lung capacity. The pulmonary airway models were created using the method presented in SCHUM and YEH (1980). The models are shown in Table 2.

Aerosol deposition in the respiratory tract was calculated using the YEH and SCHUM

\*This paper was included in Poster Session 5 and the discussion included in the summary presented in Section 12.

TABLE 1. RESPIRATORY PATTERNS USED IN DEPOSITION CALCULATIONS

| Activity                                  | Tidal volume (cm <sup>3</sup> ) | Breathing frequency (breaths min <sup>-1</sup> ) | Minute volume (l. min <sup>-1</sup> ) | Inspiratory flow rate (cm <sup>3</sup> s <sup>-1</sup> ) |
|---|---------------------------------|--|---------------------------------------|--|
| Resting                                   |                                 |  |                                       |  |

\*Negligible.

(1980) predictive aerosol deposition model. Calculations were made for particle sizes of 0.1, 0.5, 2.5, and 6.5  $\mu\text{m}$  MMAD in order to simulate realistic environmental aerosols. Predicted deposition fractions, uncorrected for deposition in the head, are reported for the tracheobronchial and pulmonary regions of the lung. Deposition efficiencies are shown in Table 3.

Nasal deposition efficiencies were estimated from YU *et al.* (1981), and are shown in Table 4. At the highest ventilation rate, it is assumed that people switch from nose to

Daily time fractions estimated from U.S. EPA (1985).

mouth breathing. The estimated daily deposition rates, corrected for nasal deposition, are shown in Table 5.

## DISCUSSION

The deposition patterns seen in Table 5 are similar to those reported by HOFMANN *et al.* (1989) and by KU and YU (1986). Total deposition rate increases as people spend a greater percentage of time at higher levels of exertion. Furthermore, at high levels of exertion children have a greater percentage of total deposition in the T-B region than

do adults for equivalent levels of activity. On a per kg basis, total deposition in the child is comparable to adults at equivalent activity levels.
