An analysis of four-prong events produced by 2.03-GeV/c π^- mesons
 ($E^* = 2.16$ GeV) in the 72-inch hydrogen bubble chamber yielded

633 events of the type $\pi^- + p \rightarrow \pi^- + p + \pi^- + \pi^+$, (1)

283 events of the type $\pi^- + p \rightarrow \pi^- + p + \pi^- + \pi^+ + \pi^0$, (2)

134 events of the type $\pi^- + p \rightarrow \pi^- + \pi^+ + \pi^- + \pi^+ + n$. (3)

We used the PACKAGE computer program (combination of PANG and KICK programs) for the track-reconstruction and fitting process. An event is found to fit Reaction (1) when it has $\chi^2 \leq 25.0$ for this reaction. It is found to fit Reaction (2) or (3) when it has $\chi^2 \leq 10.0$ for this reaction. A track-ionization examination on the scanning table helped to resolve all ambiguous events.

Using a known total cross section, we get for the cross section of Reactions (1), (2), and (3) the values $1.64 \pm .15$ mb, $0.74 \pm .08$ mb, and $0.35 \pm .04$ mb respectively.

Reaction (1)

Figure 1 shows the distribution of the effective mass of proton-pion pairs ($M_{p\pi}$) of all events of Reaction (1), (a) for $p\pi^-$ and (b) for $p\pi^+$. The $M_{p\pi^+}$ distribution shows a peak corresponding to $N_{3/2, 3/2}^*$. We estimate that about $27 \pm 3\%$ of Reaction (1) goes through the reaction $\pi^- + p \rightarrow N_{3/2, 3/2}^{*+3/2} + \pi^- + \pi^-$ with $N_{3/2, 3/2}^{*+3/2} \rightarrow p + \pi^+$. We assume that these events with $N_{3/2, 3/2}^*$ are produced according to Fig. 2 (a) (as suggested by Freda and George Salzman¹).

We base our assumption on two observations:

(a) We have plotted in Fig. 3 the distribution of the invariant-four-momentum transfer, Δ^2 , between the initial proton and final $p\pi^+$ pair for events of Reaction (1) with the effective mass $M_{p\pi^+}$ in the region of the $N_{3/2, 3/2}^*$ energy ($1.12 \text{ GeV} \leq M_{p\pi^+} \leq 1.32 \text{ GeV}$) (round points). This distribution seems to agree with the curve predicted by Salzman¹ (proportional to $((W - M)^2 + \Delta^2) / (\Delta^2 + \mu_{\pi^-}^2)^2$, where μ_{π^-} = mass of the pion, $W = M_{p\pi^+} \approx 1238 \text{ Mev}$, and M = mass of the proton, solid curve), whereas the distribution of other events of Reaction (1) (with $M_{p\pi^+} \leq 1.12 \text{ GeV}$ or $M_{p\pi^+} > 1.32 \text{ GeV}$) does not agree at all with this curve (triangular points).

(b) In diagram (a) of Fig. 2, in which the pion vertex is of the type $\pi^- + \pi^- \rightarrow \pi^- + \pi^-$, it is impossible to produce ρ mesons. This seems to be verified by our results. In Fig. 4 we have plotted the distribution of the effective mass $M_{\pi\pi}$ of the events of Reaction (1), (a) for $\pi^-\pi^-$, and (b) for $\pi^+\pi^-$. The $M_{\pi\pi}$ distribution does not show a significant peak in the region of the mass of the ρ meson. On the other hand, in the π^+ -p interaction, the corresponding diagram would be 1(b). In this diagram the pion vertex is of the form $\pi^+ + \pi^- \rightarrow \pi^+ + \pi^-$, and it is possible to produce ρ mesons. This seems to be verified by the Steinberger group,² which finds many ρ mesons in the reaction $\pi^+ + p \rightarrow \pi^+ + p + \pi^+ + \pi^-$ (about 30% of these events are $\pi^+ + p \rightarrow \pi^+ + p + \rho^0$).

Reaction (2)

Figure 5 shows the $M_{3\pi}$ distribution of all events of Reaction (2), (a) for $\pi^+\pi^-\pi^0$, and (b) for $\pi^+\pi^-\pi^0$. The $M_{\pi^+\pi^-\pi^0}$ distribution shows a peak in the region of 550 Mev corresponding to the η meson, and another peak at about 785 Mev corresponding to the ω meson. We estimate that 12 ± 4 events ($31 \pm 10 \mu\text{b}$) of Reaction (2) proceed through $\pi^- + p \rightarrow \pi^- + p + \eta$ and 55 ± 12 events ($142 \pm 31 \mu\text{b}$) through $\pi^- + p \rightarrow \pi^- + p + \omega$ with η (or ω) $\rightarrow \pi^+ + \pi^- + \pi^0$.

To verify if the ω mesons are produced by the process illustrated by the diagram 2(c) (as suggested by Sakurai³), we have plotted in Fig. 6 the distribution of the invariant-four-momentum transfer, Δ^2 , between the initial and final proton for events of Reaction (2) with $M_{\pi^+\pi^-\pi^0}$ in the mass region of the ω (760 to 820 Mev) (triangular points). This distribution does not agree with the curve predicted by the one-pion-exchange model (proportional to $\Delta^2 / (\Delta^2 + \mu_{\pi^0}^2)$ -- solid curve), whereas the Δ^2 distribution of all events of Reaction (2) (round points) agrees with this curve. The ω mesons do not, then, seem to be produced by the process illustrated by Fig. 2(c). We offer the hypothesis that the ω mesons are produced by the process illustrated by Fig. 2(d). Our hypothesis is supported by two observations:

(a) The distribution of the effective mass of the $p-\pi^-$ pairs, which are produced with a $\pi^+\pi^-\pi^0$ triplet having an effective mass in the ω mass region (Fig. 7), seems to show a peak corresponding to the $N_{3/2, 3/2}^{*-1/2}$ over the phase-space estimate (solid curve normalized over the background). This could mean that the mesons are produced via the reaction $\pi^- + p \rightarrow \omega + N_{3/2, 3/2}^{*-1/2}$, with $N_{3/2, 3/2}^{*-1/2} \rightarrow \pi^- + p$. (This evidence is rather weak, because it is difficult to know how to normalize the phase-space curve).

(b) The reaction $\pi + p \rightarrow \omega + N_{3/2, 3/2}^*$, proceeding through a pure $I = 3/2$ channel, must be much stronger for $\pi^+ + p$ (Fig. 2e) than for $\pi^- + p$. This assumption seems to be verified by the Steinberger group,² which finds that the events of the type $\pi^+ + p \rightarrow \pi^+ + p + \pi^+ + \pi^- + \pi^0$ are dominated by ω production (about 80% of these events are $\pi^+ + p \rightarrow \pi^+ + p + \omega$).

Figure 8 shows the Dalitz plot of 17 events with $540 \text{ MeV} \leq M_{\pi^+\pi^-\pi^0} \leq 550 \text{ MeV}$, of which only 12 ± 4 can be attributed to the η mesons. The points tend to be in the region of small T_{π^0} as observed by Bastien et al.⁴

Figure 9 shows the $M_{p\pi}$ distribution of events of Reaction (2), (a) for $p\pi^-$ pairs, (b) for $p\pi^+$ pairs, and (c) for $p\pi^0$ pairs. The $M_{p\pi^+}$ distribution shows the peak at $N_{3/2, 3/2}^*$ energy. Figure 10 shows the $M_{4\pi}$ distribution of all events of Reaction (2) ($\pi^+\pi^-\pi^-\pi^0$). This distribution agrees with the phase-space calculation (solid curve).

Reaction 3

Figure 11 shows the distribution of the effective mass of neutron-pion pairs of Reaction (3) events, (a) for $n\pi^+$, (b) for $n\pi^-$. The $N_{3/2, 3/2}^*$ seem to be there, but it is difficult to determine them quantitatively.

Figure 12 shows the $M_{3\pi}(\pi^\pm-\pi^\pm-\pi)$ and the $M_{4\pi}(\pi^+\pi^-\pi^+\pi^-)$ distributions of Reaction (3) events. Both distributions agree with the phase-space calculation (solid curves).

We want to thank Professor Luis W. Alvarez, Professor Donald H. Miller, and Dr. George Kalbfleisch for their encouragement and help. We are indebted to Professor Jack Steinberger for letting us know the results of his group's work before publication.
