1. INTRODUCTION

For the 1999 California Tobacco Surveys (CTS), Westat performed statistical tasks that included sample selection, weighting, and data collection. This volume of the report contains a description of the methodology used by Westat to do sample selection, weighting, and develop replicate weights for variance estimation purposes.

Three different instruments (Screener Survey, Adult Survey, and Youth Survey) were developed by UCSD and Westat for the 1999 CTS to provide data that would be comparable to the 1990, 1992, 1993, and 1996 CTS. Details on the 1999 instruments can be found in *Volume 1: Data Collection Methodology*.

The 1999 CTS utilized the list-assisted random digit dialed (RDD) method to screen eligible telephone households. This method significantly reduces the cost and time involved in such surveys in comparison to dialing numbers completely at random.

The general approach employed was a two-stage sampling procedure in which a sample of 46,590 households were screened to obtain information about the smoking status of all household members who were 10 years and older. At the second stage, extended interviews were attempted with a random sample of adults (sampling rate was based on the smoking status), and a sample of teenagers between the ages of 12 and 17.

2. SAMPLE SELECTION

Households in California that had at least one adult (aged 18 years old or older) were selected for the 1999 CTS by a random digit dialing (RDD) procedure known as the "list-assisted" sampling method. Under the list-assisted sampling method, random samples of telephone numbers were selected from banks of 100 telephone numbers that were known to contain at least one *listed* residential telephone number. Those banks with at least one listed residential telephone number are referred to as "1-plus working banks."

Nationally, only 20 percent of all numbers are working residential numbers; however about 50 percent of telephone numbers in 1-plus working banks are residences (households). Use of 1-plus working banks in the list-assisted sampling approach is not without a cost, however. The "cost" is the potential bias resulting from the exclusion of some unlisted residential telephone numbers in the "zero banks" and some residences in "new-banks." Fortunately, less than 4 percent of all telephone households (nationally) would be excluded from this sampling process.

The first step in the list-assisted sampling process involved identifying those area codes/exchanges that had any households in the target areas of interest, the 18 tobacco regions. The process of mapping area codes/exchanges into small geographical areas was not always straightforward because telephone exchanges straddled county boundaries. The sampling frame vendor (GENESYS) provided 18 *exchange coverage reports* containing all the exchanges that covered each of the 18 Tobacco Study Regions. There were some overlaps¹ of exchanges among the coverage reports. Every exchange in the coverage report was associated with a *county of plurality* (i.e., the county that had the highest percentage of listed numbers in the exchange) in the telephone numbers database provided to WESTAT by GENESYS. For sampling purposes exchanges were allocated to unique regions based on the county of plurality measure. Moreover, a few exchanges that had very high density of pagers and other non-residential hand held devices were omitted. The GENESYS database system did not contain these exchanges. The exchanges that were not considered for sampling purposes covered less than 1 percent of all the exchanges that contained the 1-plus working banks covering the State of California.

¹ About 90 percent of the exchanges covered single regions and about 10 percent of the exchanges covered two or more regions.

Based on the 1996 CTS, a preliminary estimate of about 198,000 numbers (before tritone and business purge) appeared necessary. However, more recent estimates indicated that 201,700² numbers (before tritone and business purge) were required. It is standard practice to over-sample telephone numbers by about 25 percent and release a smaller random portion to the Telephone Research Center and keep the remainder as a reserve sample. Eighteen equal probability samples within the working banks covering the 18 regions were sampled and each sample was about 25 percent larger than the minimum sample size needed. The numbers, within each region, were randomized and released as needed.

The within household sampling specifications are described in Westat's internal memorandum "1999 CTS: Specifications for within household retention rates", July 22, 1999. (See Appendix A)

² Pre-screening of these 201,700 numbers resulted in excluding 18,748 non-working (detected by 2-hit tri-tone method) and 9,087 business numbers (listed in yellow pages). The remaining 174,135 numbers were actually used to contact households in California.

3. WEIGHTING

3.1 Imputation

Four demographic variables (age, gender, race and education) were imputed if the item was missing. There were numerous reasons for item nonresponse. Some respondents did not know the answer for the item or did not wish to respond for other reasons. Some item nonresponse arose when a screener interview was interrupted and not continued later, leaving items at the end of the interview blank. Item nonresponse might have also been encountered because responses provided by the respondent were not internally consistent and this type of inconsistency was not discovered until after the interview was completed. In these cases, the items that were not internally consistent were usually set to missing (or, not ascertained) during the data editing.

Imputations were done for two reasons. First, complete responses were needed for variables used in developing the sampling weights. Second, users of the data will be computing estimates using a variety of methods and complete responses aid their analyses. But our primary purpose of item imputation was to develop sampling weights.

The order of imputation was arranged such that certain variables were imputed first so that they could be used to create cells for weighting class adjustments and for subsequent imputation. In cases in which a sort variable within a given file had missing values for some cases, all other sort variables without missing values were used to impute the sort variable with missing values prior to continuing with subsequent stages of imputation.

Prior to weighting, all missing values of four key demographic variables -- gender, race, age, and education -- were imputed. As in past CTS, the missing values of gender, race, age, and education in the screener file were imputed in two steps.

First, the key demographic values from the adult and youth interview, (gender, race, age, and education) were used to overwrite any missing data in the screener file. That is to say that if, during the screener interview, the screener respondent did not know the age or education level of another household member, and that household member was selected for an interview,

then the age or education information provided in the interview would overwrite the missing data item in the screener file.

Second, using Westat's hot-deck imputation macro, WESDECK, all remaining missing screener values were imputed.

Once all missing screener-weighting items had been imputed, the imputed screener values were used to replace the missing demographic value missing in any of the extended interview files.

3.2 Weighting Overview

The process of weighting refers to the computation of case-specific sampling weights that are necessary for producing almost unbiased estimates of the population parameters of interest. The weights are needed in the statistical analysis to compensate the variable probabilities of inclusion in the sample. Even for samples in which units are selected with equal probabilities, weighting may still be necessary to compensate for differential rates of nonresponse and deficiencies in the sampling frame. Weighting complex survey data, such as the data from this study, generally involves many steps. Computation of sampling weight components for 1999 CTS was analogous to that used for the previous CTS. The most important steps for this study are the determination of overall probabilities of selection and calculation of base weights, calculation of household weights, person-level weights, ratio adjustment (raking), and development of replicate weights.

3.3 Base Weights

The base weight of a sampling unit is defined as the reciprocal of the probability of selecting that sampling unit. The base weights are unbiased in the sense that the expected value of a weighted estimate based on the sample data is equal to the corresponding population value that would have been obtained if all the units (rather than a sample) in the frame were surveyed. A noncoverage bias results because the RDD sampling methodology excludes some eligible households.

In the list-assisted RDD method, we used an equal probability of selection of telephone numbers. The base weight for a sampled telephone number is $w = 1/f$, where f is the overall sampling rate. If a simple random sampling scheme was used, the probability of selecting n telephone numbers from a pool of N numbers is $f = n/N$.

With the use of list-assisted telephone sampling frame, all telephone numbers covering a study area have the same overall probability of selection. Thus, the probability that a household with m telephone numbers will be included in the sample is simply fm , where f is the overall sampling rate for the pool of numbers generated from the working banks of 1 or more listed numbers.

About 46,000 households that had persons 18 years and older in California were successfully screened based on about 202,000 telephone numbers selected by the 1-plus list-assisted sampling scheme. Under this scheme, 18 equal probability samples of telephone numbers were selected from 18 sampling frames -- one per each tobacco region. The base weight of a sampled telephone number is the inverse of the probability of selection.

The base weight of a telephone number selected from the frame corresponding to the i -th region is given by,

$$b_i = \frac{N_i}{n_i}, i = 1, 2, \dots, 18 ;$$

where

N_i = total number of available telephone numbers in the i -th frame; and

n_i = number of telephone numbers sampled from the i -th frame.

3.4 Household Weights

We expected about 45 to 50 percent of the sampled numbers to be residential. Since we had drawn an equal probability sample of telephone numbers from the sampling frame of all available telephone numbers, we assumed the residency rate³ for the sample is the same as the

³ Residency rate is the percentage of telephone numbers leading to households.

residency rate for all the numbers in the frame. Assuming that every residence had exactly one residential telephone number, then the household weight of a household is same as the base weight of the corresponding telephone number.

As in the past, a weighting factor of unity was assigned to households reporting one telephone number in the household and an adjustment factor of 1/2 is assigned to households with more than one residential telephone number. Technically, if the other telephone number(s) of households with multiple residential telephone numbers was in the zero-listed stratum, the household should get a weight adjustment of 1. However, the practice of looking up the other phone numbers in these households was impractical and the percent of such numbers in the zero-listed stratum is small. Eventually, the j -th household in the i -th region received a weight of:

$$h_{ij} = \begin{cases} b_i \times 0.5 & \text{If the household has more than one telephone number} \\ b_i & \text{If the household has only one telephone number} \end{cases}$$

where

b_i = the base weight for a sampled telephone number in the region.

The household weights were copied to all the three weighting files -- the screener file, adult file, and the teen file.

3.5 Person-Level Weights

As in the past CTS, all the household members were enumerated. Based on the age and smoking status, a subsample of the eligible household members was selected for an extended interview.

The k -th member of the j -th household in the i -th Tobacco Region was subsampled at a rate, r_{ijk}

$$r_{ijk} = \begin{cases} 0 & \text{if the } k\text{-th member is a child (11 yrs and younger)} \\ a_k & \text{if the } k\text{-th member is an adult (18 yrs and older)} \\ t_k & \text{if the } k\text{-th member is a teenager (12 to 17 yrs)} \end{cases}$$

$$a_k = \begin{cases} SRATE & \text{if the adult is a smoker} \\ NSRATE & \text{if the adult is a non-smoker} \end{cases}$$

$$t_k = \begin{cases} MRATE/YNUM & \text{if the teen is male} \\ FRATE/YNUM & \text{if the teen is female} \end{cases}$$

where SRATE, NSRATE, MRATE, FRATE were approximately 0.45, 0.1, 1.0, 1.0 respectively and YNUM was the number of youths in a household containing youth(s).

Note that for weighting purposes, smokers included both current and former smokers (in the last 5 years); nonsmokers were the people who never smoked or were long-term quitters (5 or more years abstinence).

The person-level weights were constructed for all the eligible household members. The person-level base weight of the k -th member of the j -th household in the i -th region is w_{ijk} , where

$$w_{ijk} = \begin{cases} 0 & \text{if } r_{ijk} = 0; \text{ and} \\ h_{ij} / r_{ijk} & \text{if } r_{ijk} > 0. \end{cases}$$

4. RATIO ADJUSTMENT (RAKING)

Theoretically, if the sample was strictly obtained by a probabilistic scheme and there is no nonresponse, then the total of the sample weights should be the population total. But in practice, this is not so due to many factors. Two important factors that contribute to the deviation of weights are nonresponse and noncoverage due to sampling only telephone households covered by selected telephone exchanges. Forcing the weights to known population totals reduce the nonresponse and noncoverage. This technique is called post stratification and it is a popular estimation procedure in which the weights of the respondents are adjusted so that the sum of the adjusted weights is equal to known population totals.

Since post stratification involves adjusting the weights of the respondents, the post-stratified estimates are different than the estimates produced without post stratification and the variances of the estimates are also different. Post stratification is often used to reduce the variance of the estimates. Since post stratification is used so frequently and it affects the estimates and their precision, a facility for post stratifying weights has been generally incorporated in software programs that analyze complex survey data, such as WesVarPC (available for free from Westat).

Indexing the cell identifiers by c , where $c=1, \dots, L$ (for example region by the age by gender cells), the weights are first summed by cell

$$\hat{W}_c = \sum_{i \in c} w_i,$$

where w_i is the weight of the respondent i that fell in cell c .

Next, the multiplicative post stratification adjustment factor for cell c is computed as

$$A_c = \frac{N_c}{\hat{W}_c},$$

where N_c is the control total for cell c .

The post-stratified weight is the weight multiplied by the post stratification adjustment factor corresponding to the correct cell

$$PW_i(c) = A_c w_i \text{ for } i \in c$$

Raking ratio estimation, or simply raking, can be considered as post stratification performed iteratively in order to control two (or more) known marginal population totals. Raking was first proposed by Deming and Stephan (1940)⁴ as a way of assuring consistency between complete count and sample data from the 1940 U.S. Census of Population. Typically, raking is used in situations where the interior cells of a cross tabulation are either unknowns, or some sample sizes in the cells are too small for efficient estimation. Oh and Scheuren (1987)⁵ provide a concise description of the raking procedure and its properties.

In raking, the marginal population totals, N_i and N_j are known (say, age and sex population counts), however, the interior cells of the cross-tabulation N_{ij} (the age by sex cells) are estimated from the sample by \hat{N}_{ij} , where these are the sum of the weights in the cells. The raking algorithm proceeds by proportionately scaling the \hat{N}_{ij} , such that the following relations are satisfied:

$$\sum_j \hat{N}_{ij} = N_i$$

and

$$\sum_i \hat{N}_{ij} = N_j$$

It has been shown (e.g., Ireland and Kullback, 1968⁶) that, under some regularity conditions if only the N_i and N_j are known, then the estimates, \hat{N}_{ij} , obtained by raking to convergence are asymptotically unbiased, normally distributed and minimum variance.

The person-level weights were raked to recent California population counts. The needed controls are presented in Appendix B, Tables B-1 to B-11.

⁴ Deming, W.E., and Stephan, F.F. (1940). On a least square adjustment of a sampled frequency table when the expected marginal totals are known. *Annals of Mathematical Statistics* 11, 427-444.

⁶ Ireland, C.T., and Kullback, S. (1968). Contingency tables with given marginals. *Biometrika* 55, 179-188.

4.1 Screener Sample

All screened households were assigned their household-level weights, h_{ij} . These base weights then were raked in two dimensions. The first dimension was defined by region and gender, while the second was defined by race (Hispanic, white, black, and other), age (0-11, 12-17, 18-24, 25-44, and 45+), and education (0-11, 12, and 13+). Appendix B, Tables B-1 and B-2 contain the control counts.

4.2 Youth Sample

For the Youth file, three raking dimensions were used. Region and gender defined the first dimension, race and age (12-14, 15-17)⁷ defined the second, and the third dimension was defined by race and education status of the head of the household. The population estimates for the latter dimension were obtained from the weighed screener data. Appendix B, Tables B-3, B-4, and B-5 contain the needed control counts.

4.3 Adult Sample

The person-level weights for adults were raked in five dimensions. The first dimension was defined by region and gender; the second dimension was defined by race and age; third, fourth, and fifth dimensions involved smoking status; and the various distributions of adult smoking status by education, gender, and age were derived from the weighted screener data. The control totals used for these dimensions are described in Appendix B, Tables B-6 to B-11.

⁷ While smoking status was collected at the Screener interview for all household members age 10 years and older, only those age 12 years – 17 years were eligible for the Youth interview.

5. VARIANCE ESTIMATION

When data are collected as part of a complex sample survey, there is often no easy way to produce approximately unbiased and design-consistent estimates of variance analytically. The variance of survey statistics, including means and proportions, estimated using standard statistical packages such as SAS or SPSS, are inappropriate and usually too small. A class of techniques called *replication methods* provides a general method of estimating variances for the types of complex sample designs and weighting procedures usually encountered in practice. The basic idea behind the replication approach is to select subsamples repeatedly from the whole sample, to calculate the statistic of interest for each of these subsamples, and then to use the variability among these subsample or replicate statistics to estimate the variance of the full sample statistics. There are different ways of creating subsamples from the full sample. The subsamples are called *replicates* and the statistics calculated from these replicates are called *replicate estimates*.

Replication is not the only way to compute the variance of statistics from complex samples; however, it is able to handle complex sampling designs, complex estimates, and complex weighting schemes. Replication can be used where other methods are not easily applicable. This method also has some advantages even when other methods, such as Taylor series approximation, can be applied

One of the main advantages of the replication approach is its ease of use at the analysis stage. The same estimation procedure is used for the full sample and for each replicate. The variance estimates are then readily computed by a simple procedure. Furthermore, the same procedure is applicable to most statistics desired such as means, percentages, ratios, correlation, and so forth. These estimates can also be calculated for analytic groups or subpopulations. It is not even necessary for the analyst to understand the sampling or estimation methods if the replicate weights are included with the data.

Analogous to the previous CTS, for the 1999 survey the jackknife method of replication was used for estimation of sampling errors. This method employs the full sample estimate, \hat{q} , and replicate estimates, \hat{q}_r , ($r = 1, \dots, R$) for a parameter of interest, q , to estimate the sampling error of \hat{q} using the following estimator:

$$v(\hat{q}) = \frac{R-1}{R} \sum_{r=1}^R (\hat{q}_r - \hat{q})^2$$

In order to remain consistent with the replicate structure of the previous CTS, a set of 51 replicate groups was generated. The data file was first sorted according to the 18 regions and then assigned to the replicate groups based on the order of sample (telephone number) selection. The calculation of replicate weights proceeded as follows.

First, each of the screened householders was assigned the appropriate final person-level base weight in each of the 51 replicate groups. In the next step, replicate base weights were adjusted to reflect the deletion of that portion of the sample which is excluded for formation of respective replicates (i.e., the full sample base weight of all nondeleted units in each replicate were multiplied by 51/50). Each of the resulting 51 sets of replicate base weights were then raked to the same control counts used for raking of the full sample weights.

1999 California Tobacco Survey

MEMORANDUM

TO: P. Nicchitta, S. Noble, F. Tirmazi, J. Wernimont July 22, 1999
M. Aiken, K. Hubbell, D. Maklan, E. Mehl, D.
Morganstein
FROM: Joe Croos
SUBJECT: 1999 CTS: Specifications for within household retention rates

This memorandum contains specifications necessary to retain a youth and/or adult(s) within a cooperating household.

Roster

In the 1999 CTS, we would roster up to 15 members of a household. All household members will be entered in a roster. Each member will be assigned a random number (RANDOM01-RANDOM15). These random numbers were already chosen and loaded in the CATI load file. Table 1 contains the layout of the CATI load file.

Adult

We assume that all screener respondents are adults (>17 years). One or more adults may be selected for the extended interview based on their smoking status. The smoking status of each person except children below 10 years will be ascertained as follows:

Smoking Status	Frequency of Smoking	Responses to Screener Questions
Smoker	Current	SC10 = 1, 2 or (SC9 = 1, -7, -8 and SC10 = -7, -8)
Smoker	Recent Former	SC9 = 1, -7, -8, SC10 = 3, SC11=1, and SC12 = 1
Smoker	5 Year Former	SC9 = 1, -7, -8, SC10 = 3, SC11=1, and SC12 = 2, -7, -8
Nonsmoker	Long Term Quitter	SC9 = 1, -7, -8, SC10 = 3 and SC11 =2, -7, -8
Nonsmoker	Zero or Small Amount Smoker	SC9 = 2, and SC10 = 3, -7, -8

An adult (>17 years or if age is missing) should be retained ("retain" means we attempt to administer an extended adult interview) according to his/her smoking status, with the following retention rate:

Smoker SRATE (initially SRATE = 0.45)
Nonsmoker NSRATE (initially NSRATE = 0.10)

If the random number assigned to an adult-smoker is \leq SRATE (initially 0.45), then retain. If the random number of an adult-nonsmoker \leq NSRATE (initially 0.10), then retain.

Youth

The selection process of a youth (12 to 17 years) in the 1999 CTS is different from the 1996 CTS. We plan to retain (“retain” means we attempt to administer a youth interview) only one youth per household (from households containing youths). Also, we plan to set different retention rates for males and females. The initial retention rate for both males and females will be 100%, but if we feel the coverage rate of one gender is different from that of other, we would adjust one of the retention rates to compensate for differential coverage rates.

Let YNUM = number of youths in a screened household, FRATE = retention rate of female, MRATE = retention rate of male, and YSAMP = indicates whether first or second random youth was selected. (When YNUM = 0, there will be no youth interview.).

For each cooperating household with youth, do:

Case 1: YNUM = 1

- Initialize YSAMP = 0; Set YSAMP = 1 if the youth is retained;
- If the youth is FEMALE, retain¹ at a rate of FRATE (initially FRATE = 1);
- Else, if the youth is MALE, retain at a rate of MRATE (initially MRATE = 1);
- Else, if the gender is unknown² (variable SEX is blank/missing) then retain (at a rate of 1);
- Quit (go to next HH)

Case 2: YNUM > 1

- Initialize YSAMP = 1;
- Select a youth at random³
- If the selected youth is FEMALE, retain at a rate of FRATE (initially FRATE = 1);
- Else, if selected youth is MALE, retain at a rate of MRATE (initially MRATE = 1);
- If the youth is retained, then quit (go to next HH);
- Else, select another⁴ youth at random and retain (i.e. retain at a rate of 1 regardless of the gender) and set YSAMP = 2;
- Quit (go to next HH)

¹ That is, retain if YRANDOM is \leq FRATE.

² In 1996 CTS, we had about 0.12% of the ENUM records with missing SEX. We expect no more than 10 completed youth interviews with missing SEX. We plan to impute the missing SEX.

³ A random selection can be done by sorting by the random number assigned to each in the roster (RANDOM01-15) and select the first in the randomly sorted list.

⁴ The next youth in randomly sorted list of youths.
