Abstract

It can be difficult to uncover the truth when presented with two conflicting beliefs. Adults integrate beliefs in a rational way by placing more weight on beliefs held with high confidence than beliefs with low confidence. Here, we investigate the development of this rational integration in 5- to 10-year-old children. Children at all ages selected the higher confidence belief if confidence differed, and older children (8-10) preferred an integrated belief when two informants presented beliefs with equal confidence. We interpret this as evidence that children use expressed confidence to inform rational decision-making, consistent with the principles of rational cue combination.
