INTERNATIONAL OPTIMISM

4

Abstract

Objective: The current exploratory study sought to examine dispositional optimism, or the general expectation for positive outcomes, around the world.

Method: Dispositional optimism and possible correlates were assessed across 61 countries ($N = 15,185$; mean age = 21.92; 77% female). Mean-level differences in optimism were computed along with their relationships with individual and country-level variables.

Results: Worldwide, mean optimism levels were above the midpoint of the scale. Perhaps surprisingly, country-level optimism was negatively related to GDP per capita, population density, and democratic norms and positively related to income inequality and perceived corruption. However, country-level optimism was positively related to projected economic improvement. Individual-level optimism was positively related to individual well-being within every country, although this relationship was less strong in countries with challenging economic and social circumstances.

Conclusions: While individuals around the world are generally optimistic, societal characteristics appear to affect the degree to which their optimism is associated with psychological well-being, sometimes in seemingly anomalous ways.

International Optimism: Correlates and Consequences of
Dispositional Optimism Across 61 Countries

It is well established that positive thinking is related to positive life outcomes. Optimistic individuals tend to be healthier, more satisfied in their romantic relationships, and more successful at their jobs (for a review, see Carver & Scheier, 2014). Although the physical, social, and psychological correlates of dispositional optimism are well-studied, nearly all the research has been restricted to individuals from W.E.I.R.D. populations (Western, Educated, Industrial, Rich, Democratic; Henrich, Heine & Norenzayan, 2010) and, more specifically, was conducted in the U.S.

The current paper reports an exploratory study of dispositional optimism, or the general expectation for positive outcomes, across 61 countries. We first describe cross-country variation in mean-level optimism and its relations with country-level variables. We then assess relations between individual levels of optimism and other individual difference measures, including personality and psychological well-being, and explore gender differences. Finally, we explore country-level moderators of links between optimism, individual differences, and psychological well-being.

Optimism as Related to Individual Characteristics

A large body of research has established relationships between dispositional optimism and other aspects of personality (Marshall, Wortman, Kusulas, Hervig, & Vickers, & 1992; Mattis, Fontenot, & Hatcher-Kay, 2003; Neff, Rude, & Kirkpatrick, 2007; You, Fung & Isaacowitz, 2009). Optimism is positively related to extraversion, agreeableness, conscientiousness, and emotional stability (Chang & Sanna, 2001; Scheier, & Carver, 1992; Vickers & Vogeltanz, 2000), with the strongest relationships observed with extraversion and

INTERNATIONAL OPTIMISM

6

1
2
3 emotional stability (Sharpe et al., 2011). Thus, we would expect consistent relationships between
4
5 optimism and these individual differences across countries, although this expectation has not
6
7 heretofore been empirically tested.
8
9

10 Unlike the consistent findings concerning personality traits, research investigating gender
11
12 differences has produced mixed results. In a pioneering assessment of dispositional optimism,
13
14 researchers found no gender difference (Williams, 1992). However, one study found that young,
15
16 well-educated women tend to be more optimistic on average relative to their older, less educated
17
18 male counterparts (Gallagher, Lopez & Pressman, 2012).
19
20

Optimism and Well-Being

21
22
23
24 Many studies have assessed links between optimism and indicators of well-being (see
25
26 Carver et al., 2010 for a review). Optimism is positively related to general psychological well-
27
28 being (Alarcon, Bowling, & Khazon, 2013; Dember & Brooks, 1989; Scheier & Carver, 1992;
29
30 Scheier, Carver, & Bridges, 2001) and subjective happiness (Augusto-Landa, Pulido-Martos, &
31
32 Lopez-Zafra, 2011; Gallagher & Lopez, 2009; Lyubomirsky & Lepper, 1999; Neff et al., 2007;
33
34 Scheier, & Carver, 1992) and negatively related to neuroticism (Brebner, Donaldson, Kirby, &
35
36 Ward, 1995; Scheier et al., 1994) and psychological distress (Chang & Sanna, 2001; Creed,
37
38 Patton, & Bartrum, 2002). One review theorized that optimism is an adaptive trait that enables
39
40 individuals to perceive desirable outcomes as possible and use coping strategies to actively
41
42 alleviate negative emotions during stressful circumstances (Scheier & Carver, 1992). Indeed,
43
44 among individuals undergoing a distressing event, those higher in dispositional optimism
45
46 evaluate their circumstances less negatively as they utilize more productive coping strategies
47
48
49
50
51
52
53
54
55
56
57
58
59
60 (Carver & Gaines, 1987; Carver et al., 1993; Scheier et al., 1989).

INTERNATIONAL OPTIMISM

7

The role of culture in the strength or direction of these relations has received little empirical attention. Long established in the fields of anthropology, sociology, and economics is the notion that country-level indicators of quality of life predict individual-level well-being (Bonini, 2008; Jones & Klenow, 2010; Slottje, 1991; Stroup, 2007; Veenhoven, 1999). But even though optimism is consistently related to individual well-being, it may also be true that societal circumstances play a role in the degree to which individuals' optimism is psychologically beneficial – a possibility that will be investigated in the present study.

Cross-Cultural Variation in Optimism

A few recent investigations have begun to illuminate the ways in which culture might be associated with mean levels of optimism around the world. A recent study used the Gallup World Poll data to examine cross-country variability in individuals' predictions of future subjective socioeconomic status, which researchers used as a proxy for dispositional optimism (Gallagher, Lopez, & Pressman, 2012). Although the researchers had to rely on this imperfect proxy, their analysis demonstrated that across 142 countries, most individuals had favorable expectations, and on the individual level, this optimistic projection was consistently associated with higher levels of subjective well-being and subjective health across countries (Gallagher et al., 2012).

Additionally, a meta-analysis of 213 studies from 22 countries (Fischer & Chalmers, 2008) focused on cross-cultural variation in mean-level optimism scores, assessed using the revised version of the Life Orientation Test (LOT-R), and the association between each country's average level of optimism and various culture-level value dimensions (i.e., power distance, egalitarianism, individualism, uncertainty avoidance, masculinity, autonomy, harmony, and SES). The researchers concluded that the variability in mean-level optimism scores was fairly

INTERNATIONAL OPTIMISM

8

small across countries, yet countries with higher optimism tended to be higher in egalitarianism and individualism (Fischer & Chalmers, 2008).

Overview and Research Questions

The current study examined optimism's relationship with individual- and country-level variables across 61 countries. We further sought to illuminate cultural variability in these relationships by examining the interaction between optimism, well-being, and country-level indicators of cultural quality of life. Specifically, we had four exploratory research questions:

1. Does dispositional optimism vary across countries?
2. What country-level variables are associated with variation in the mean level of optimism across countries?
3. Are individual levels of optimism associated with personality traits and individual well-being, and do these associations vary across countries?
4. Are country-level indicators of quality of life associated with variation in the relationships between optimism, individual characteristics, and well-being?

Method**Participants**

Participants ($N = 15,185$; 77% female) were recruited by local collaborators in 61 countries (see Table 1) and were members of college communities (average age = 21.92, $SD = 1.71$). Participants either volunteered or received extra credit, course credit, small gifts, or monetary compensation for their participation.

Procedures

The data reported in this article stem from the International Situations Project, a large cross-cultural study assessing situational experience, daily behavior, and individual differences.

INTERNATIONAL OPTIMISM

1
2
3 Participants were directed by a local study coordinator to the study's custom-made website
4
5 (ispstudy.net). After providing informed consent, participants completed a series of individual
6
7 difference measures. Participants then had the opportunity to receive feedback on their
8
9 personality trait levels (for an English-language wireframe of the data-gathering website see
10
11 <https://osf.io/r4q8p/>).

Measures

12
13
14
15
16
17 As stated previously, the current analyses are part of a larger study that seeks to explore
18
19 cross-country variation and similarity of situational experience and individual differences. We
20
21 chose variables that we believed would accomplish this broad goal. The present study included
22
23 measures of individual differences that have been previously associated with dispositional
24
25 optimism, including the Big Five and their facets, Honesty-Humility and its facets, Narcissism,
26
27 Religiosity, and two measures of happiness. Cronbach's alpha coefficients ranged from .49
28
29 (admiration facet of narcissism) to .91 (religiosity).¹

INTERNATIONAL OPTIMISM

1

1
2
3 For non-English speaking countries, international collaborators (all of whom are
4 psychologists) translated each measure into the local language; these translations were then
5 compared with the English original through back-translation and adjusted for discrepancies.
6
7
8
9
10 Research materials were translated into 39 languages.²

11
12 **Dispositional optimism.** Participants completed the 6-item Life Orientation Test-
13 Revised (LOT-R; Carver, Scheier & Segerstrom, 2010; e.g., “In uncertain times, I usually expect
14 the best”; 1 = *strongly disagree*, 5 = *strongly agree*). For brevity’s sake, we removed four filler
15 items of the original LOT-R. See Sweeny & Falkenstein (2016) for evidence supporting the
16 appropriateness of removing the LOT-R filler items.
17
18
19
20
21
22

23
24 **Personality.** The Big Five personality traits along with three facets of each were
25 measured using the 60-item BFI-2 (Soto & John, 2017; four items represent each facet), as
26 follows: extraversion (sociality, assertiveness, energy), agreeableness (trust, respect,
27 compassion), conscientiousness (productiveness, responsibility, organization), openness to
28 experience (intellect, aestheticism, creativity), and negative emotionality (sometimes called
29 *neuroticism*, the inverse of emotional stability: anxiety, depression, emotionality-moodiness).

57
58
59
60

Participants responded to each of 60 statements (e.g., “I am someone who is outgoing”) on a
five-point scale (1 = *disagree strongly*, 5 = *agree strongly*).

Participants completed the 10-item Honesty-Humility subscale (e.g., “I wouldn’t use
flattery to get a raise or promotion at work, even if I thought it would succeed”; 1 = *strongly
disagree* to 5 = *strongly agree*) of the HEXACO (facets: sincerity, fairness, greed, modesty;
Ashton & Lee, 2009). Participants also completed the Narcissistic Admiration and Rivalry
Questionnaire (NARQ; Back et al., 2013; e.g., “I deserve to be seen as a great person”; “Other

² Translations of all measures used in the ISP are available at <https://www.situationslab.com/translations>.

INTERNATIONAL OPTIMISM

people are worth nothing”; 1 = *strongly disagree*, 5 = *strongly agree*), as well as the Religiosity scale of the Social Axioms Survey (Leung et al., 2012; e.g., “Belief in a religion helps one understand the meaning of life”; 1 = *strongly disbelieve*, 5 = *strongly believe*).

Happiness. Happiness was measured using the Subjective Happiness Scale (SHS; Lyubomirsky & Lepper, 1999) and the Interpersonal Happiness Scale (IHS; Hitokoto & Uchida, 2015). The SHS, developed in the U.S., is a 4-item scale (e.g., “In general, I consider myself...” 1 = *not a very happy person*, 7 = *a very happy person*), and the IHS, developed in Japan, is a 9-item scale (e.g., “I believe that I and those around me are happy”; 1 = *strongly disagree*, 5 = *strongly agree*).

Country-level variables. The current analyses utilized previously and separately collected country-level variables publicly available from various sources. We cast a wide net to identify associations of broad interest, especially seeking country-level variables that captured social, political, and economic properties as well as societal values of many, if not all, of the countries included in our sample.

We first gathered variables from The World Bank (2016; databank.worldbank.org) including employment rate (for 58 countries; employment to population ratio for individuals over the age of 15; averaged across 2013-2016), life expectancy (for 60 countries; in years), income inequality (for 43 countries; GINI index), infant mortality rate (for 58 countries; deaths per 1,000 live births), and human development, a composite variable comprising several demographic and economic indicators of quality of life (for 60 countries; Human Development Index, United Nations Development Program, 2016). Additionally, country-level suicide rate was gathered from the World Health Organization (for 58 countries; age-standardized, per 100,000 deaths; World Health Organization, 2012).

INTERNATIONAL OPTIMISM

3

1
2
3 For 60 of our countries, we collected estimates for gross domestic product (GDP) per
4 capita, population density (i.e., people per square-kilometer of land area), projected and actual
5 growth in GDP from the International Monetary Fund (imf.org). GDP projected growth was
6 assessed as the projected change in GDP to 2020; GDP actual growth was assessed as the
7 measured change in GDP since 2016.
8
9

10
11
12 For 59 of our countries, we accumulated variables relevant to satisfaction with life from
13 the World Happiness Report (Helliwell, Layard, & Sachs, 2016). These indicators were
14 quantified as the average binary ratings by country for questions relating to each of the
15 following: freedom of choice (“Are you satisfied or dissatisfied with your freedom to choose
16 what you do with your life?”), perceptions of corruption (“Is corruption widespread throughout
17 the government or not?”; “Is corruption widespread within businesses or not?”), confidence in
18 government (“Do you have confidence in each of the following, or not?”; “How about the
19 national government?”), and democratic quality (various indicators of voice, accountability, and
20 political stability as accumulated by Worldwide Governance Indicators project; Kaufmann,
21 Kraay, & Mastruzzi, 2011).

33
34
35
36
37

38 For 57 countries in our sample, previous research using the Schwartz Value Survey
39 provided data concerning cultural values along seven dimensions (Schwartz, 2001; 2008):
40 harmony (valuing the group rather than the self), mastery (valuing success through self-
41 assertion), embeddedness (focus on sustaining order and tradition), hierarchy (reliance on
42 structured and hierarchical social roles), egalitarianism (valuing cooperation and concern for all),
43 affective autonomy (the independent pursuit of pleasure), and intellectual autonomy (the
44 independent pursuit of ideas and knowledge).

4

1
2
3 Finally, for 33 countries, we obtained variables from the Organization for Economic Co-
4 operation and Development (OECD) Better Life Index (Better Life Index, 2016;
5 <http://www.oecdbetterlifeindex.org/>). These included country-level scores for homicide rate
6 (homicides per 100,000 people), personal safety (percentage of people who report feeling safe
7 walking alone at night), long work hours (percentage of individuals who work over 50 hours per
8 week), and leisure time (average number of hours spent on leisure and personal care, including
9 sleeping and eating).

19 **Assessing measurement equivalence of optimism across countries.** Before proceeding
20 with our primary analyses, we addressed the comparability of the measurement of dispositional
21 optimism across countries using a method that is feasible in large-scale, multi-country studies
22 (Bryne & von de Vijver, 2010). Given that the meaning of each item of a psychological measure
23 can be defined by its relationship with the other items, one method for assessing measurement
24 comparability of optimism across countries is to assess how similarly participants within each
25 country interpret the items of the LOT-R.

26
27
28
29
30
31
32
33
34
35 In line with this logic, we used the Matrix Comparison approach suggested by Gardiner
36 et al. (2019) that is especially suitable for comparing measures across a large number of
37 countries. First, we correlated each item of the LOT-R with every other item, producing a 6 x 6
38 matrix within each of the 61 countries. Next, we constructed an intercorrelation matrix of these
39 matrices, relating each country's inter-item correlation matrix with each other country's matrix.
40 These analyses produced a 61 x 61 correlation matrix that represented the similarities of the
41 items' meanings (i.e., the pattern of LOT-R inter-item correlations) between two countries.
42 These correlations can also be interpreted as indicators of factorial invariance, because the factor
43 structure of an instrument derives directly from the intercorrelations of its items.

1
2
3 The average correlation was $r = .91$, ranging from $r = .997$ (Serbia and Greece) to $r = .54$
4 (Malaysia and Indonesia). To evaluate these correlations, we used as a reference point the
5 average similarities of inter-item correlation patterns among subgroups within single countries.
6 Specifically, we generated inter-item matrices for the data gathered within six U.S. states and
7 within two cities in the 11 countries for which multi-site data are available. The average inter-
8 item matrix correlation across states in the U.S. and multiple cities within various countries was r
9 = .96. Taken together, this matrix comparison approach revealed that the degree of within-
10 country similarity in LOT-R interpretation is not much greater (.96 vs. .91) than between-country
11 similarity in interpretation (see Supplementary Materials, Table 2). These results indicate
12 factorial invariance, but not necessarily scalar invariance, the equivalence of the interpretation of
13 means. Scalar invariance is an ideal, rarely, if ever, achieved in large cross-cultural studies, and
14 we suggest that the association between country-level mean scores and other variables – such as
15 reported later in this paper – are reasonable and informative indicators of the implications of
16 mean-level variation.

Results

17
18
19 The data that support the findings of this study are openly available on the Open Science
20 Framework at <https://osf.io/tgfrx/>.

Country-Level Variation in Optimism

22
23 Average optimism scores across countries ranged from 3.08 (Singapore) to 3.87
24 (Estonia), with a world average of 3.41 (see Table 2). Estonia, Mexico, Nigeria were among the
25 highest in optimism, and Singapore, Japan, Hong Kong were among the lowest. Although
26 optimism did not show large mean-level differences across countries ($SD = .20$ on a 5-point

INTERNATIONAL OPTIMISM

1
2
3 scale), multilevel modeling (level 1 = individuals, level 2 = countries) revealed that individuals'
4 level of optimism did vary depending on country of residence; ICC(1) = .07 (see Table 2).
5
6

7
8 Next, we assessed the correlations between country-level optimism and other country-
9 level variables. We organized these variables into three broad categories: societal characteristics
10 (e.g., employment rate, Human Development Index (HDI), democratic quality), quality of life
11 (e.g., life expectancy, infant mortality, personal safety), and cultural values (e.g., harmony,
12 egalitarianism; see Table 3).
13
14
15
16
17
18

19 Within the category of societal characteristics, country-level optimism scores were,
20 perhaps surprisingly, positively related (at $p < .001$) to average perceptions of corruption and
21 negatively related to HDI and democratic quality (all $ps < .001$, see Table 3). Optimism was
22 also positively related to projected growth in GDP, a variable that is associated with low
23 *current* GDP per capita and other positive country-level markers (i.e., countries that are worse
24 off generally have higher projected growth) (this relationship was significant at $p < .01$ rather
25 than $p < .001$ so perhaps should be interpreted with caution). In contrast, optimism was not
26 significantly related to actual recent GDP growth.
27
28
29
30
31
32
33
34
35
36
37

38 For indicators of quality of life, country-level optimism scores were positively
39 associated with infant mortality and negatively associated with life expectancy. Among
40 indicators of cultural values, "embedded values" (focused on culture and tradition) were
41 positively related to country-level optimism (at $p < .001$), whereas both affective autonomy and
42 intellectual autonomy were negatively related (at $p < .01$).

57
58
59
60

INTERNATIONAL OPTIMISM

7

and their facets, honesty-humility, narcissism, religiosity, gender, and subjective and interdependent happiness.

In 60 out of 61 countries (exception: Uganda), a significant relationship emerged between optimism and extraversion (Table 4; $\beta = 0.38$ [95% CI: .36, .41]; $t = 29.39$, $p < .001$). Similarly, in 60 out of 61 countries (exception: Indonesia), a consistent negative relationship emerged between optimism and negative emotionality ($\beta = -0.49$ [-.52, -.45]; $t = -29.68$, $p < .001$). Associations between optimism and agreeableness were also generally positive, albeit less robust, as were associations between optimism and conscientiousness. Optimism was inconsistently associated with openness, honesty-humility, religiosity and narcissism across countries. Results for the facets of each trait generally followed the patterns just described (see Supplemental Materials). For all individual difference measures assessed, there was significant variation across countries in their relationship with optimism (see Table 4). Finally, there was a small but significant gender difference in mean levels of optimism worldwide, (Table 2; female world average = 3.37, male world average = 3.41; $t = 2.48$, $p = .01$). This trend did not vary by country ($\beta = 0.005$ [-.01, .03], $t = 0.50$, $p = .61$). With one exception (Indonesia), consistent positive relationships emerged between optimism and both subjective happiness ($\beta = 0.58$ [.55, .60], $t = 42.82$, $p < .001$) and interdependent happiness ($\beta = 0.45$ [.42, .48], $t = 62.58$, $p < .001$).

Country-Level Moderators of Associations with Well-Being

Finally, we ran a series of multilevel models to examine variability in the relationships between optimism and markers of well-being. We ran models assessing the relationship between optimism and each marker of well-being, accounting for nesting at the country level, followed by a series of model fit comparisons between a model with fixed slopes between optimism and well-being (*Model 1*) and a model which allows these relationships to vary by

INTERNATIONAL OPTIMISM

8

country (*Model 2*). Results revealed a significant change in the Chi square between models, indicating there was significant variation across countries in the relationships between optimism and well-being (see ΔX^2 column in Table 4).

To explain this variation, we examined interaction effects with country-level variables. In these analyses we treated markers of well-being as outcome variables rather than predictor variables given that well-being varies within-person across time and circumstances (Lucas, 2007), whereas dispositional optimism is relatively stable. In addition, we chose *a priori* to focus our analyses on six country-level indicators that provide a sense of the country's degree of development (Bérenger & Verdier-Chouchane, 2007): GDP per capita, GDP projected growth, GDP actual growth, income inequality, life expectancy, infant mortality, and human development³.

For these analyses, we ran a series of models predicting markers of well-being from the interaction between individual-level optimism and various country-level indicators. These models, examined individually, are presented in Table 5. In countries with higher GDP per capita, longer life expectancy, lower infant mortality rates, higher human development, and lower income inequality, optimism was more strongly related to happiness (positively) and negative emotionality (inversely) relative to countries with lower GDP per capita, shorter life expectancy, higher infant mortality, and greater income inequality. Moreover, in countries with low GDP projected growth, optimism was more positively related to happiness and more negatively related to negative emotionality relative to countries with high GDP projected growth. No such relationship was observed for GDP actual growth.

³ The inclusion of Human Development in these analyses done at the suggestion of a reviewer, and thus was not *a priori*.

INTERNATIONAL OPTIMISM

9

1
2
3 Taken together, these results indicate that for individuals who live in more developed
4 countries with a relatively stable projected GDP, optimism is a stronger predictor of well-being
5 than for individuals who live in less developed countries where GDP is projected to increase.
6
7 Figures 1a-1g provide a graphic representation of these relationships. For instance, in Figure 1a,
8 correlations between wellbeing and optimism and various measures of well-being (including
9 negative indicators, such as depression) increase in strength as GDP per capita increases,
10 whereas in Figure 1b, these same correlations generally decrease as projected *growth* in GDP
11 increases.

Discussion

26
27
28 Our investigation had the ambitious goal of examining dispositional optimism through a
29 global lens. As we will address below, our study takes a large leap beyond previous research that
30 was largely restricted to “WEIRD” samples toward understanding the nature, predictors, and
31 potential consequences of optimism in 61 countries varying widely in their economic, societal,
32 and political characteristics.
33
34
35
36
37
38
39

Country-Level Associations

40
41
42 Given the wide range of countries included in our dataset, we were able to investigate
43 whether the limited but detectable variability in optimism across countries was predictable based
44 on societal characteristics, quality of life, or cultural values. Perhaps surprisingly, people in
45 countries that appear to experience more challenging circumstances reported higher levels of
46 dispositional optimism. Concerning cultural values, people in more traditional societies and
47 countries that de-emphasize individual autonomy were higher in dispositional optimism on

59
60

INTERNATIONAL OPTIMISM

10

1
2
3 average. No result contradicted this general pattern, although some country-level indicators were
4
5 unrelated to optimism. We can only speculate, but three possible explanations for this trend can
6
7 be offered.
8
9

10 First, people might use their compatriots as a reference point when evaluating their future
11
12 outlook (Heine, Lehman, Peng & Greenholtz, 2002). Our participants were members of college
13
14 and university communities, whose circumstances may be relatively comfortable compared to
15
16 many of the people around them, particularly in less developed countries.
17
18

19 Second, people might develop an optimistic outlook as a type of psychological armor
20
21 when circumstances are particularly challenging. Dispositional optimism can and does change
22
23 over time and across situations (e.g., Segerstrom et al., 2007), which leaves open the possibility
24
25 of some degree of functional adaptation.
26
27

28 Third, recall that lower quality of life is associated with higher projected growth in GDP
29
30 (see Supplementary Materials), and the projected growth in GDP is associated with optimism. At
31
32 its core, optimism is about the future, not the present. Therefore, it may be in countries where
33
34 things seem likely to improve – even when current conditions are poor – where optimism tends
35
36 to thrive. To test this supposition, we related country-level variables with negative emotionality,
37
38 an overlapping, yet non-future oriented variable. Results from these exploratory analyses reveal
39
40 less consistent relationships with country-level variables, signaling to the importance of
41
42 optimism's future-oriented nature.
43
44
45

46 Finally, it is important to note that although we cannot be certain why our results differ
47
48 from those reported in Fischer and Chalmers' (2008) meta-analysis, our study was distinct from
49
50 their effort in a number of ways. Most notably, they took a meta-analytic approach, gathering
51
52 existing studies rather than collecting new data. The practical effects of this distinction are that
53
54
55
56
57
58
59
60

INTERNATIONAL OPTIMISM

11

1
2
3 their data are older (the meta-analysis was conducted in 2006; our data were collected in 2017-
4
5 2018) and less consistent in the methods by which they were gathered across different
6
7 subsamples of participants.
8
9

Individual-Level Associations

10
11
12 Our study was also well-suited to examine within-country, individual-level associations
13
14 between optimism and personal characteristics. First, we largely replicated previous findings
15
16 linking optimism to Big Five personality traits, notably strong and consistent associations with
17
18 extraversion and emotional stability. Although dispositional optimism is not typically listed
19
20 among the core personality traits, considerable evidence points to its trait-like nature (e.g.,
21
22 stability over time, heritability, robust behavioral consequences; see Carver et al., 2010).
23
24
25

26
27 On average, female participants were significantly less optimistic than their male
28
29 counterparts, although mean differences were quite small (a .03 difference on a 5-point scale).
30
31 These findings are in contrast to Gallagher et al.'s (2012) analysis of the Gallup World Poll data
32
33 in which women were *more* optimistic. However, the Gallup data used individuals' predictions
34
35 of future subjective socioeconomic status as a rough proxy for optimism, whereas the present
36
37 study used the well-validated LOT-R.
38
39

40
41 Concerning well-being, our study replicated a robust literature linking dispositional
42
43 optimism to psychological well-being (e.g., Gallagher & Lopez, 2009; Neff et al., 2007).
44
45 However, despite a consistent bivariate relationship between optimism and well-being, further
46
47 analyses revealed variability in those relationships, such that dispositional optimism may be
48
49 more strongly related to happiness, anxiety, and depression in highly developed countries
50
51
52
53
54
55
56
57
58
59
60

INTERNATIONAL OPTIMISM

12

1
2
3 compared to less developed countries⁴. One possible explanation for these findings is that in less-
4 developed countries, current circumstances may be a stronger driver of well-being; where people
5 are facing difficulties overall, the benefits of an optimistic outlook for well-being may be
6 attenuated. Likewise, in more- developed countries, individuals may not be as generally affected
7 by their cultural circumstances (because they are not as severe and also perhaps less variable)
8 and thus are able to draw on their optimism to boost their well-being. Another possible
9 explanation can be derived from the finding that less-developed countries also had greater
10 projected future economic growth. Thus, it is possible that to the extent that people in such
11 countries are aware of indicators of future growth, they might develop an optimistic outlook that
12 is not associated with their current, possibly low level of well-being. This finding deserves
13 replication and further investigation, but it suggests that simply being dispositionally optimistic
14 is insufficient to reap its full benefits; the surrounding cultural situation limits or promotes its
15 powers of positivity.

54
55
56
57
58
59
60

A fundamental limitation of this and most cross-cultural research, is the relative homogeneity of our sample with regard to age and education. On the one hand, the fact that the majority of our participants across countries were sampled from college communities makes differences between countries easier to interpret because country of residence is the principal variable that distinguishes between our samples – not affluence, education, or age. On the other hand, our samples may restrict the range of optimism. For example, perhaps individuals with access to higher education are in a position that promotes an optimistic outlook, namely one that

⁴ We investigated the possibility that these findings arose because the LOT-R and SHS and the IHS had lower alpha reliabilities in countries with higher GDP/lower projected growth. However, these correlations declined only slightly when each measure was corrected for attenuation (the four r 's = .20, -.20, .31, and -.30, respectively).

INTERNATIONAL OPTIMISM

13

1
2
3 is socioeconomically more comfortable, and pursuing higher education in order to improve one's
4 future prospects is, almost by definition, an optimistic enterprise.
5
6

7
8 These conflicting possibilities illuminate the need to test the generalizability of optimism
9
10 across age groups. To do so, we compared mean-levels of optimism from four countries in our
11 sample that recruited members from both college and non-college communities (China, Ukraine,
12 Serbia, and Turkey). There were no significant differences between these college and community
13 samples in Ukraine, Serbia, and Turkey. In China, participants from college communities were
14 somewhat lower in dispositional optimism ($M = 3.37$) than their non-college community
15 counterparts ($M = 3.47$; $t = 2.22$, $p = .03$; see Supplementary Materials). These findings do not
16 support any strong or universal differences in optimism between college and community
17 samples. Nonetheless, casting a larger net to capture within-country variability in age and
18 socioeconomic circumstances is a crucial next step for this area of research.
19
20
21
22
23
24
25
26
27
28
29

30
31 Finally, future work should extend the current project and assess country-level predictors
32 of cross-country variation in the relationship between optimism and physical health, which was
33 not assessed in the present study.
34
35
36

37 Conclusions

38
39
40 Although many questions and opportunities for future research remain, the present
41 investigation provides a rare glimpse at how a trait—one identified, conceptualized, and largely
42 studied using W.E.I.R.D. samples (mostly in the US) looks on an international stage. Our
43 findings highlight both the similarities and differences in human experience across a wide array
44 of countries. People's level of dispositional optimism is generally high across the world, as are
45 its associations with other traits and broad measures of happiness—yet our findings also warn
46 against the perils of assuming complete cultural invariance because some of these associations
47
