### Abstract

Alveologenesis is the culmination of lung development and involves the correct temporal and spatial signals to generate the delicate gas exchange interface required for respiration. Using a novel Wnt signaling reporter system, we demonstrate the emergence of a Wnt-responsive alveolar epithelial cell sublineage that arises during alveologenesis called the axin2<sup>+</sup> alveolar type 2 cell or AT2<sup>Axin2</sup>. The number of AT2<sup>Axin2</sup> cells increases substantially during late lung development, correlating with a wave of Wnt signaling during alveologenesis. Transcriptome analysis, *in vivo* clonal analysis, and *ex vivo* lung organoid assays reveal that AT2s<sup>Axin2</sup> promote enhanced AT2 cell growth during generation of the alveolus. Activating Wnt signaling results in expansion of

AT2s whereas inhibition of Wnt signaling inhibits AT2 cell development and shunts alveolar epithelial development towards the alveolar type 1 cell lineage. These findings reveal a wave of Wnt-dependent AT2 expansion required for lung alveologenesi and maturation.

## Graphical abstract

## INTRODUCTION

Generation of the alveolus requires intricate interactions between multiple cell lineages to create the complex structure responsible for gas exchange in mammals (Morrisey and Hogan, 2010). Epithelial, mesenchymal, and endothelial cell lineages combine to expand the saccular structure at the distal tips of the branched airways starting around embryonic day 16.5 (E16.5) in mice (Whitsett and Weaver, 2015). Soon thereafter, this rudimentary structure remodels and promotes epithelial and mesenchymal cell communication, which helps integrate the developing vascular network. Remodeling of the alveolus continues postnatally concomitant with specification and maturation of alveolar type 1 (AT1) and type 2 (AT2) epithelial cells until lung maturity is reached at postnatal day 30 (PN30) in mice and into adolescence in humans (Branchfield et al., 2016; Herring et al., 2014; Mund et al., 2008). Despite the extensive knowledge of earlier stages of lung development including branching morphogenesis, little is known about the cell lineage specific interactions and molecular pathways governing the normal generation of the lung alveolus (Branchfield et al., 2016; El Agha et al., 2014; Yun et al., 2016). Since disruption of this process can be deleterious and result in neonatal diseases such as bronchopulmonary dysplasia (BPD) (Bourbon et al., 2005), a better understanding of the cellular growth and differentiation that occurs during this crucial stage of lung development is required.

Wnt signaling is a critical pathway important for self-renewal and specification of stem cells in multiple organs (Clevers et al., 2014). Components of the Wnt pathway are expressed in specific patterns during early lung development, and previous work has demonstrated

essential roles for Wnt signaling in lung endoderm specification and early development (Cohen et al., 2009; De Langhe et al., 2008; Goss et al., 2009; Konigshoff and Eickelberg, 2010; Li et al., 2005; Li et al., 2002; Mammoto et al., 2012; Maretto et al., 2003; Miller et al., 2012; Okubo and Hogan, 2004; Rajagopal et al., 2008; Shu et al., 2005; Shu et al., 2002; van Amerongen et al., 2012). However, what role if any Wnt signaling plays in later stages of lung epithelial differentiation and maturation is unclear. Using a novel Wnt signaling reporter mouse line (*Axin2<sup>CreERT2-TdTom</sup>*), we reveal a previously unknown wave of Wnt signaling during alveologenesis. The *Axin2<sup>CreERT2-TdTom</sup>* reporter demarcates a sublineage of AT2s called AT2s<sup>Axin2</sup>, which emerges at the onset of alveologenesis. AT2s<sup>Axin2</sup> promote lung organoid formation in *ex vivo* assays and have greater clonal growth potential *in vivo* during alveologenesis. Importantly, activation of Wnt signaling in the overall AT2 population elicits a similar self-renewal response, promoting enhanced organoid formation, increased proliferation, and increased clonal expansion during alveologenesis. Conversely, inhibition of Wnt signaling in the overall AT2 lineage inhibits organoid formation and AT2 self-renewal and shunts their differentiation towards the AT1 lineage. These data demonstrate a critical role for Wnt signaling during lung alveologenesis through expansion of the AT2 population via proliferation and balancing the ratio of AT2-AT1 cells.

## RESULTS

### The *Axin2<sup>CreERT2-TdTom</sup>* mouse line reveals dynamic Wnt-responsiveness during lung development

The Wnt signaling pathway is critical for lung endoderm specification and patterning of the branching lung and mesenchyme (Cohen et al., 2009; Goss et al., 2009; Harris-Johnson et al., 2009; Kadzik et al., 2014; Li et al., 2002; Miller et al., 2012; Mucenski et al., 2003; Rajagopal et al., 2008; Volckaert and De Langhe, 2015). However, the role for Wnt signaling during lung sacculation and alveologenesis is poorly understood. We have generated a novel Wnt signaling reporter mouse line to identify, purify, and characterize Wnt responsive lineages during lung development. The *Axin2<sup>CreERT2-TdTom</sup>* allele has an expression cassette consisting of a tamoxifen-inducible Cre recombinase linked to a TdTomato fluorescent protein by a 2A self-cleaving peptide inserted into the start codon of the mouse *Axin2* gene (Figure S1A). Using this reporter line, we show that *Axin2*<sup>+</sup> cells, marked by TdTomato expression, become restricted to the distal epithelium and the surrounding mesenchyme at E13.5 (Figure 1A and 1B). To track *Axin2*<sup>+</sup> cells earlier in lung development, we crossed the *Axin2<sup>CreERT2-TdTom</sup>* mouse with the R26R<sup>EYFP</sup> line and initiated a lineage trace at E10.5. Examination of *Axin2<sup>CreERT2-TdTom</sup>·R26R<sup>EYFP</sup>* lungs at E14.5 shows that *Axin2*<sup>+</sup> cells give rise to both proximal and distal lung epithelium and mesenchyme, corroborating previous data demonstrating the presence and importance of Wnt signaling in early lung development and the multipotency of the early lung endoderm (Figure 1C) (Al Alam et al., 2011; Goss et al., 2009; Mucenski et al., 2003; Shu et al., 2005).

As lung development progresses, the branching lung epithelium is patterned into distinct proximal and distal compartments (Morrisey and Hogan, 2010; Swarr and Morrisey, 2015). The emergence of these two compartments coincides with diminished Wnt-responsiveness

with the few responsive cells confined to the Sox9+/Sox2- distal lung endoderm (Figure 1D and 1E).

By E17.5, lung sacculation is underway and the rudimentary alveolus expands to prepare the distal lung for the alveologensis stage, where the saccules remodel to refine and expand the surface area required for high efficiency gas exchange in the postnatal period (Proadhan and Kinane, 2002). Axin2+ cells are found in the lung mesenchyme from E17.5-E18.0 to postnatal day 4 (P4) (Figure S1B-E), with only a small increase in the number of Pdgfr $\beta$ + mesenchymal cells during this phase (Figure S1J). In contrast, distinct changes occurred in the cellular composition of Wnt responsiveness in the maturing lung epithelium during this time frame. At E17.5-E18.0, a small number of Axin2+ proximal and distal epithelial cells exist (Figure 1F-I and 1N). As development progresses through the saccular stage and into the alveologensis stage at P4, the number of Axin2+ secretory epithelial cells and Axin2+ AT1 cells decreased, and the Axin2+ multi-ciliated cells remained rare (Figure 1J-L). The remaining Axin2+ secretory epithelial cells were confined to the region surrounding Pgp9.5+ neuroendocrine bodies (Figure S1K and L). In contrast, a dramatic increase in the number of Axin2+ AT2 (AT2s<sup>Axin2</sup>) cells was observed (Figure 1I, M, N). This change represents an approximate six-fold increase in AT2s<sup>Axin2</sup> during this late stage of sacculation into early alveologensis (Figure 1N). By P4, greater than 97% of all Axin2+ epithelial cells are Sftpc+ AT2s (Figure 1O). These data reveal that Wnt responsive cells become restricted to the distal epithelium during sacculation and subsequently to a subpopulation of AT2s during alveologensis.

We observed both a bright and dim TdTomato expressing population of cells in the lung at P4. To verify how faithful TdTomato expression correlated with Axin2 expression, we performed FACS and qPCR analysis of TdTomato expressing cells in the lung. Importantly, we recently showed that our *Axin2*<sup>CreERT2-TdTom</sup> mouse line faithfully recapitulates Axin2 expression and Wnt responsiveness in the intestinal crypts (Li et al., 2016). We observed both a dim and bright population of TdTomato expressing cells in the lung and Axin2 expression correlated with the levels of TdTomato expression in these two populations (Figure S2A and D). Furthermore, analysis of FACS-isolated cells using endogenous TdTomato expression and antibodies specific for epithelium (EpCAM) and Pdgfra+ (CD140a) mesenchymal lineages demonstrates that the epithelial cells are TdTomato dim and most of the mesenchymal cells are TdTomato (Figure S2B, C, E, F).

### A wave of Wnt signaling appears in AT2s prior to alveologensis

Our results suggest a wave of Wnt signaling occurs in the AT2 lineage coinciding with alveologensis and maturation of the lung (Figure 2A). Careful examination for Wnt responsiveness between E17.5-E18.0 and P30 reveal that most AT2s<sup>Axin2</sup> arise postnatally (Figure 2B-2G). The AT2<sup>Axin2</sup> cells are scattered randomly throughout the alveolus with very occasional clustering of cells (Figure 2I). AT2<sup>Axin2</sup> cells increase throughout the postnatal period and persist through P30 (Figure 2H and I). To determine whether the AT2s<sup>Axin2</sup> are fixed sublineage fate or a dynamic state during alveologensis, we performed a 3 week tamoxifen chase at P4 in *Axin2*<sup>CreERT2-TdTom</sup>:*R26R*<sup>EYFP</sup> mice. Using FACS-based analysis, we noted that while many AT2<sup>Axin2</sup> cells were both TdTomato and YFP double

positive, there was a significant proportion of cells were YFP single positive and TdTomato single positive, suggesting that some AT2<sup>Axin2</sup> cells lose their Wnt-responsiveness and some non-Axin2<sup>+</sup> cells gain Wnt-responsiveness over time (Figure S2G and H). Confirmatory immunohistochemical staining corroborated these findings (Figure S2I and J).

Using lineage tracing with the *Axin2*<sup>CreERT2-TdTom</sup>·*R26R*<sup>EYFP</sup> mice, we found that Axin2<sup>+</sup> endothelial and mesenchymal cell lineages remained mostly unchanged between E17.5-E18.0 through P10 (Figure S3A-H). However, we did observe a significant increase in alveolar epithelial progeny with little change in the bronchiolar epithelium when lineage traced from P4 to P10 (Figure S3I-O). Closer analysis of alveolar epithelial lineages shows that this increase is due to the marked expansion of lineage traced Axin2<sup>+</sup> AT2s and not AT1s from P4 to P10 (Figure S3P).

Gene expression analysis on AT2s FACS isolated from *Sftpc*<sup>CreERT2</sup>·*R26R*<sup>EYFP</sup> E18.5 and P4 lungs revealed a 2-fold increase in *Axin2* mRNA during this stage of lung development (Figure 2M and 2N). To verify that the increase in *Axin2* expression correlates with an increased number of AT2<sup>Axin2</sup> cells, we used FACS to isolate Axin2<sup>+</sup> epithelial cells from *Axin2*<sup>CreERT2-TdTom</sup> lungs at P4 (Figure 2O) and subjected them to extracellular staining for the AT1 marker Pdpn and intracellular staining for the AT2 marker Sftpc (Figure S4A-C). When compared to E18.5 Axin2<sup>+</sup> epithelial cells, there was a 2-fold increase in the number of AT2<sup>Axin2</sup> cells at P4 with a concomitant reduction in the number of Axin2<sup>+</sup> AT1s (Figure 2P). Of note, the efficiency of intracellular staining for Sftpc is around 50% (Figure S4D-G). Thus, a wave of Wnt signaling occurs during late sacculation into early alveologenesis that activates this pathway in a sublineage of AT2s called AT2<sup>Axin2</sup> cells which are important for alveolar growth and maturation.

### The AT2<sup>Axin2</sup> sublineage promotes alveologenesis by promoting growth of the alveolar epithelium *in vivo*

AT2s undergo a significant increase in cell number during alveologenesis (Yang et al., 2016). To examine the proliferative potential of the AT2<sup>Axin2</sup> population, we performed *in vivo* clonal analysis using the *R26R*<sup>Br2.1</sup> reporter and 5-ethynyl-2-deoxyuridine (EdU) incorporation in the total AT2 population versus the AT2<sup>Axin2</sup> sublineage. *Sftpc*<sup>CreERT2</sup>·*R26R*<sup>Br2.1</sup> and *Axin2*<sup>CreERT2-TdTom</sup>·*R26R*<sup>Br2.1</sup> pups were administered tamoxifen at P4 followed by a chase to P30 (Fig. 3A and B). The average clone size differed between the AT2 and AT2<sup>Axin2</sup> sublineage with the AT2<sup>Axin2</sup>-derived clones being larger (1.49 cells/clone for total AT2 vs. 1.65 cells/clone for AT2<sup>Axin2</sup>,  $P < 0.02$ ) (Figure 3C). Importantly, the number of multi-cellular clones generated by the AT2<sup>Axin2</sup> sublineage was significantly greater than the overall AT2 population. While the AT2<sup>Axin2</sup> sublineage contained predominantly two and three cell clones, the majority of clones from the total AT2 population were comprised of one and two cells (Figure 3D). These data suggest that AT2s<sup>Axin2</sup> have an increased ability for growth and expansion during lung alveologenesis.

Next, we directly assessed the proliferative potential of the AT2<sup>Axin2</sup> population at P4 and compared it to the overall AT2 lineage using EdU labeling (Salic and Mitchison, 2008). Following a short chase of 2 hours, lungs were harvested and immunostained to examine EdU incorporation, Sftpc, and RFP expression (Figure 3E-3H). Approximately 3% of the

total AT2 lineage are proliferating at P4. Of this proliferating AT2/Sftpc+ population, 70% are AT2<sup>Axin2</sup> cells while approximately 30% are the Sftpc+ non-AT2<sup>Axin2</sup> population (Figure 3I). These results suggest that AT2<sup>Axin2</sup> cells preferentially drive alveolar growth and expansion.

### The AT2<sup>Axin2</sup> sublineage is highly enriched in genes important for lung alveogenesis

To define the gene expression characteristics behind the enhanced proliferation in the AT2<sup>Axin2</sup> sublineage we performed transcriptome analysis on *Sftpc*<sup>CreERT2:R26R<sup>EYFP</sup></sup> and *Axin2*<sup>CreERT2-TdTom</sup> P4 AT2 cells obtained by FACS. Principal component analysis using two variables illustrates significant gene expression differences between the total AT2 populations and the AT2<sup>Axin2</sup> sublineage (Figure 4A). There were 4,101 differentially regulated genes between total AT2 and AT2<sup>Axin2</sup> cells (see Supplemental Table 1 and GEO accession number GSE82154). Functional enrichment analysis of molecular functions and biological processes indicates that the AT2<sup>Axin2</sup> sublineage is highly enriched in multiple biological processes associated with alveogenesis. These include the cell cycle, vascular development, and extracellular matrix production and interactions (Figure 4B). Interestingly, genes involved in metabolism/lipid metabolism, a function associated with mature AT2s, are down-regulated in AT2<sup>Axin2</sup> cells. Despite this finding, AT2<sup>Axin2</sup> cells express known AT2 marker genes such as *Sftpc* and *Abca3* at levels equal or similar to the total AT2 population (Figure 4C and 4D). AT2<sup>Axin2</sup> cells do not express or do not express different levels of early distal endoderm genes including *Sox9*, *Id2*, or *Foxp2*, indicating that they do not represent an immature developmental progenitor (see GEO accession number GSE82154). Importantly, the transcriptome data demonstrated that the AT2<sup>Axin2</sup> sublineage expresses growth factor signaling components known to play important roles in lung development and stem cell biology including *Fgf18*, *Shh*, *Bmp4*, *Tgfb2*, *Vegf*, and *Myb* (Figure 4E-4L). In addition, enrichment of Wnt ligand, receptors, and co-receptors were observed in AT2<sup>Axin2</sup> cells compared to the AT2 total population (Supplemental Table 2). These data indicate that the AT2<sup>Axin2</sup> sublineage is distinct from the AT2 population in general and suggest that they act as signaling hubs for alveolar growth and differentiation.

### Increased Wnt signaling activity enhances *ex vivo* lung organoid formation from alveogenesis stage AT2s

To further characterize the ability of the AT2<sup>Axin2</sup> sublineage to promote alveolar growth during the alveogenesis stage of lung development, we took advantage of an *ex vivo* lung organoid model and adapted it for use in early postnatal lung alveolar epithelium (Barkauskas et al., 2013). FACS was used to isolate AT2s from *Sftpc*<sup>CreERT2:R26R<sup>EYFP</sup></sup> and AT2<sup>Axin2</sup> cells from *Axin2*<sup>CreERT2-TdTom</sup> P4 pups. Five thousand isolated Sftpc+ or Axin2+ alveolar epithelial cells were co-cultured with 50,000 adult lung fibroblasts to form lung alveolar organoids (Figure 5A and 5B). Quantification of colony forming efficiency (CFE) demonstrated an increase in CFE for the AT2<sup>Axin2</sup> sublineage compared to the total Sftpc+ AT2 population (Figure 5C). Both total AT2s and AT2s<sup>Axin2</sup> have the ability for self-renewal (Figure 5C), and both are capable of multi-lineage differentiation as noted by expression of Sftpc and Pdpn for AT2 and AT1 cells, respectively (Figure 5D-5G).

Wnt signaling and Wnt-responsiveness have been shown to be important for intestinal organoid growth and Wnt agonists are used for standard organoid culture (Farin et al., 2016; Farin et al., 2012; Yin et al., 2014). Therefore, we asked whether activating Wnt signaling in the overall AT2 cell lineage would result in enhanced organoid formation. Treatment of the AT2 lineage with Wnt3a resulted in a significant increase in CFE (Figure 5H-L). Conversely, treating with the Wnt ligand secretion inhibitor IWP-2 (Chen et al., 2009), resulted in inhibition of lung organoid formation, which was partially rescued with addition of Wnt3a to the culture media (Figure 5K and L). Importantly, AT2<sup>Axin2</sup> cells lose TdTomato expression after they are placed in culture (Figure S5A-C), likely due to disruption of the alveolar niche. Treatment with recombinant Wnt3a can maintain TdTomato expression (Figure S5D), suggesting that a persistent Wnt signal is required for continued organoid formation.

### Wnt activation promotes clonal expansion of AT2 cells during alveologenesis *in vivo*

Our *ex vivo* lung organoid assays suggest that AT2<sup>Axin2</sup> cells promote alveolar growth during alveologenesis. To determine whether Wnt signaling is important for alveolar epithelial growth *in vivo*, we generated *Sftpc*<sup>CreERT2</sup>;*Ctnnb1*<sup>fl(Ex3)/+</sup>;*R26R*<sup>EYFP</sup> to activate Wnt/β-catenin signaling using the activated β-catenin allele (*Ctnnb1*<sup>fl(Ex3)/+</sup>) (Harada et al., 1999). Of note, activating Wnt/β-catenin with the *Axin2*<sup>CreERT2-TdTom</sup> allele results in rapid neonatal lethality due to non-pulmonary related defects, precluding their use in these studies. Wnt/β-catenin signaling was activated by tamoxifen treatment at P4 and lungs were examined at P30. *Sftpc*<sup>CreERT2</sup>;*Ctnnb1*<sup>fl(Ex3)/+</sup>;*R26R*<sup>EYFP</sup> lungs exhibited increased cellularity with an increase in AT2 cell number (Figure 6A-6C and Figure S6A and S6B). Proliferation was increased by more than three-fold in *Sftpc*<sup>CreERT2</sup>;*Ctnnb1*<sup>fl(Ex3)/+</sup>;*R26R*<sup>EYFP</sup> AT2s compared to control mice (Figure 6D-6F).

To determine whether activation of Wnt/β-catenin signaling promoted clonal expansion of AT2 cells during alveologenesis, we utilized *Sftpc*<sup>CreERT2</sup>;*Ctnnb1*<sup>(+/+)</sup>;*R26R*<sup>Br2.1</sup> and *Sftpc*<sup>CreERT2</sup>;*Ctnnb1*<sup>fl(Ex3)/+</sup>;*R26R*<sup>Br2.1</sup> treated with tamoxifen at P4 to track the expansion of AT2 cells. Wnt activation in AT2s resulted in a significant increase in clone size compared to control mice after four weeks (Figure 6G-I). Whereas the clone size distribution ranged from one to three clones with predominantly one cell clones in control mice, *Sftpc*<sup>CreERT2</sup>;*Ctnnb1*<sup>fl(Ex3)/+</sup>;*R26R*<sup>Br2.1</sup> mutant mice developed clones ranging from one cell to six cells with the majority of clones containing two or more cells (Figure 6J). These data indicate that AT2s with enhanced Wnt activity exhibit increased clonal expansion.

Recent data in adult mice suggest that AT1 and AT2 cells can exhibit bidirectional differentiation (Barkauskas et al., 2013; Jain et al., 2015). Therefore, we examined the relative ratios of AT2s and AT1s in *Ctnnb1*<sup>fl(Ex3)/+</sup> mutant mice and compared them with their control mice counterparts. We performed lineage tracing from P4 to P30 in mice with the *R26R*<sup>Br2.1</sup> reporter that can outline the extended structure of AT1s and AT2s derived from Sftpc<sup>+</sup> cells with CFP, YFP, GFP, or RFP. In addition we utilized the *R26R*<sup>EYFP</sup> reporter with subsequent antibody staining for Aqp5 and Sftpc. We found no significant differences in the percent of lineage traced AT2s versus AT1s in the two groups examined

(Figure 6K-6M and S6C), suggesting that activation of Wnt signaling did not affect AT2-AT1 differentiation at this stage of development.

### **Inhibition of Wnt signaling impedes AT2 cell expansion and shunts differentiation towards the AT1 lineage during lung alveologenesis**

To examine the impact of loss of Wnt/ $\beta$ -catenin signaling on AT2 proliferation and differentiation during lung alveologenesis, we generated *Sftpc<sup>CreERT2</sup>;Ctnnb1<sup>fl/fl</sup>;R26R<sup>EYFP</sup>* to conditionally delete  $\beta$ -catenin in AT2s at P4 and analyze alveolar development through P30. Loss of  $\beta$ -catenin in AT2s at this stage of lung development did not appear to grossly alter lung morphology (Figure S7A and S7B). However, immunostaining revealed a statistically significant decrease in AT2s (Figure S7C-E). Likewise, there was a notable 2.5-fold decrease in AT2 proliferation as measured by Ki67 staining (Figure 7A-7C).

Interestingly, loss of  $\beta$ -catenin expression in *Sftpc<sup>CreERT2</sup>;Ctnnb1<sup>fl/fl</sup>;R26R<sup>Br2.1</sup>* mutants, resulted in a marked increase in the number of AT1 cells in the clones derived from *Sftpc*+AT2s (Figure 7D-7F). These findings suggested that Wnt signaling normally restricts the differentiation of the AT2 lineage into the AT1 lineage during lung alveologenesis. To further corroborate whether Wnt signaling is essential for the restriction of AT2-AT1 differentiation, we generated *Sftpc<sup>CreERT2</sup>;Ctnnb1<sup>fl/fl</sup>;R26R<sup>mTmG</sup>* mutants and controls to outline the full cell surface of lineage traced cells (Muzumdar et al., 2007). Following induction of recombination at P4, *Sftpc<sup>CreERT2</sup>;Ctnnb1<sup>fl/fl</sup>;R26R<sup>mTmG</sup>* mutant mice produced an approximately five-fold increase in lineage traced AT1 cells (Figure 7G-7I). These studies reveal dynamic Wnt-responsiveness in late lung development that promotes AT2 growth and inhibits differentiation of AT1 cells during alveologenesis (Figure 7J).

## **DISCUSSION**

Generation of the lung alveolus is the definitive step in the development of a functional respiratory unit for gas exchange. Pathway-mediated differentiation and maintenance of alveolar epithelial cell populations during alveologenesis have remained a poorly understood aspect of lung development. While a role for Wnt signaling in promoting early lung distal endoderm progenitor fate has been described (Shu et al., 2005; Volckaert et al., 2013), the pathways mediating later saccular and alveolar epithelial development are less understood. Our data indicate that Wnt signaling, an important regulator of early lung development, is reactivated during alveologenesis to provide a wave of AT2 cell growth for the final important stages of lung growth and development.

Wnt signaling plays critical roles during early lung endoderm specification, branching morphogenesis, and lung mesenchymal development (Cohen et al., 2009; De Langhe et al., 2008; Goss et al., 2009; Kadzik et al., 2014; Konigshoff and Eickelberg, 2010; Li et al., 2005; Li et al., 2002; Mammoto et al., 2012; Maretto et al., 2003; Miller et al., 2012; Okubo and Hogan, 2004; Rajagopal et al., 2008; Shu et al., 2005; Shu et al., 2002; van Amerongen et al., 2012). Our data now show that as lung development progresses, Wnt-responsiveness in lung epithelial cells wanes until early alveologenesis, when there is a re-emergence of Wnt-responsive alveolar epithelial cells called AT2s<sup>Axin2</sup>. While previous studies have examined some aspects of the structural remodeling that occurs during the alveolar stage of

lung development (Amy et al., 1977; Bourbon et al., 2005; Branchfield et al., 2016; Massaro and Massaro, 2007), little is known about how the alveolus expands during early postnatal lung growth and in particular the molecular pathways that regulate this process. As the lung grows into its final mature size in the adult, the AT2 and AT1 lineages expand to accommodate this growth. However, recent studies suggest that AT1 and AT2 cell expansion is not balanced during alveologenesis. While AT1s stop proliferating during the first few days after birth, AT2s continue to proliferate and expand throughout alveologenesis (Yang et al., 2016). This difference may be due to the ability of the AT1 cell to dramatically remodel and spread over a great distance in the alveolus, allowing it to grow through cellular remodeling rather than proliferation (Wang et al., 2016; Weibel, 2015; Yang et al., 2016). Given the role that the AT2 lineage plays in synthesis of pulmonary surfactant and as an important monitor of the innate immune response, the ability to expand and grow during alveologenesis likely allows the lung in general to respond to challenges during this critical early postnatal period of life (Mulugeta et al., 2015). Our data shows that the re-emergence of Wnt signaling promotes growth of the postnatal alveolar epithelium and balances the epithelial composition of the alveolus through control of AT2-AT1 differentiation.

Disruption in alveolar growth underlies many important pediatric lung diseases including bronchopulmonary dysplasia (Bourbon et al., 2005). Moreover, premature infants that are born prior to the completion of alveologenesis often have long-term consequences including impaired lung function and pulmonary hypertension (Islam et al., 2015; Stenmark and Abman, 2005). While clinicians have recognized the importance of alveologenesis in lung function for many decades, the basic understanding of the cellular interactions and molecular pathways involved in promoting this late developmental process has remained an enigma. Cellular proliferation is generally thought to be low during this developmental period but our data suggests that AT2 cell expansion, primarily through expansion of the AT2<sup>Axin2</sup> sublineage, plays a critical role in postnatal alveolar growth. The wave of Wnt signaling that occurs during early postnatal lung alveologenesis identified in the present study is critical for the final stages of lung development by promoting a burst of AT2 expansion to meet the needs of the adult organ. Interestingly, while loss of  $\beta$ -catenin-dependent Wnt signaling in AT2s results in the transition of some of the AT2 population into AT1s, further increases in  $\beta$ -catenin-dependent Wnt signaling did not result in inhibition of AT2 to AT1 differentiation. This suggests that there is a threshold of Wnt signaling required to maintain the AT2 fate, and an additional increase in Wnt signaling only promotes AT2 cell proliferation. As such, studies pharmacologically modulating Wnt signaling following experimental injury could provide important insight into whether this pathway could be used therapeutically to treat neonatal lung disease.

## EXPERIMENTAL PROCEDURES

### Animals

Description and genotyping information regarding *Ctnnb1<sup>fl/fl</sup>*, *Ctnnb1<sup>fl(Ex3)/+</sup>*, *R26R<sup>EYFP</sup>*, *R26R<sup>Br2.1</sup>*, and *R26R<sup>mTmG</sup>* mouse lines has been previously described (Brault et al., 2001; Harada et al., 1999; Madisen et al., 2010; Muzumdar et al., 2007; Snippert et al., 2010). The *Sftpc<sup>CreERT2</sup>* mouse line was a generous gift from Hal Chapman at UCSF, and its

construction has been previously described (Chapman et al., 2011). The *Axin2<sup>CreERT2-TdTomato</sup>* mouse was constructed by inserting an expression cassette, consisting of a creERT2 cDNA linked to a 2A self-cleaving peptide sequence linked to a TdTomato cDNA, into the start codon of the *Axin2* locus. Full details on the construction of this reporter line are available upon request. All animal studies were performed under guidance of the University of Pennsylvania Institutional Animal Care and Use Committee.

### Tamoxifen induction of cell lineage tracing

Tamoxifen (Sigma) was dissolved in 100% ethanol and diluted with corn oil (Sigma) to produce a 10% ethanol:tamoxifen:corn oil mixture at 20 mg/mL. Mice were injected intraperitoneally (IP) with the indicated doses to induce recombination based on the observed efficiency of each cre and reporter line. For lineage tracing in *Sftpc<sup>CreERT2</sup>* mice, they were IP injected with 100 µg/gm of mouse for the *R26R<sup>EYFP</sup>* and *R26R<sup>mTmG</sup>* alleles. For clonal analysis using the *R26R<sup>Br2.1</sup>* allele, 5-10 µg/gm was used. Induction of recombination in *Axin2<sup>CreERT2-TdTomato</sup>* P4 pups was accomplished using 100 µg/gm of mouse for the *R26R<sup>EYFP</sup>* and *R26R<sup>mTmG</sup>* alleles and 200 µg/gm for the *R26R<sup>Br2.1</sup>* allele.

### Histology

Lungs were inflated with 2% paraformaldehyde under constant pressure of 30 cm water and allowed to fix overnight. Tissue was embedded in paraffin and sectioned. Hematoxylin and eosin staining was performed to examine tissue morphology. Immunohistochemistry was used to detect protein expression using the following antibodies on paraffin sections: GFP (chicken, Aves, 1:500), GFP (goat, Abcam, 1:100), RFP (rabbit, Rockland, 1:250), Nkx2.1 (rabbit, Santa Cruz, 1:50), Sox2 (rabbit, Seven Hills, 1:500), Sox9 (rabbit, Santa Cruz, 1:100), Pecam (rat, HistoBioTec, 1:20), SM22α (goat, Abcam, 1:100), Pdgfra (rabbit, Cell Signaling, 1:50), Pdgfra (goat, R&D Systems, 1:50), Pdgfrβ (rabbit, Cell Signaling, 1:100), Pdgfrβ (goat, R&D Systems, 1:400), Scgb1a1 (goat, Santa Cruz, 1:20), Tubb4 (mouse, BioGenex, 1:20), Sftpc (rabbit, Millipore, 1:250), Sftpc (goat, Santa Cruz, 1:50), Pdpn (mouse, Hybridoma Bank, 1:50), Aqp5 (rabbit, Abcam, 1:100), and Ki67 (rabbit, Abcam, 1:50).

### Quantification of alveolar epithelial cell number

Immunostaining using the indicated cell lineage specific markers was used to identify lineage traced alveolar epithelial cell types. Confocal microscopy using a Leica TCS SP8 confocal scope was employed to capture images. For each mouse, confocal Z-stack images were taken in at least 10 random alveolar areas. All images were subject to ImageJ software analysis. Cell counts were performed manually using the Cell Counter plug-in for ImageJ. At least 10 different regions of each lung or 1000 cells were counted for each mouse.

### Quantification of proliferation

Proliferation was assessed using either the Click-iT EdU Alexa Fluor 647 Imaging Kit (ThermoFisher Scientific) or Ki67 immunostaining. For proliferation analysis using EdU, P4 pups were administered 50 mg/kg EdU via IP injection. Two hours post injection, the lungs were harvested for tissue processing as described previously. Following double

immunostaining for RFP and Sftpc, lung sections were processed with the Click-iT EdU reaction. Z-stack optical sections were attained via confocal microscopy and 10 independent alveolar fields of view were assessed for RFP, Sftpc, and EdU expression. Cell counts were performed using ImageJ software.

### Quantification of clonal analysis

Clonal analysis was performed after induction of recombination at P4 followed by a four-week chase. Lungs were harvested as described and fixed overnight in 2% paraformaldehyde. The next day, the lungs were washed with PBS for 2 hours. The lungs were embedded in OCT compound (Fisher HealthCare) and frozen on dry ice and ethanol. 12  $\mu$ m lung sections were cut and subjected to immunostaining for Sftpc to identify all AT2s followed by counterstaining with DAPI (4',6-diamidino-2-phenylindole). At least 10 Z-stack sections were analyzed from random fields. Each single-colored clone was analyzed for number of cells in each clone. Single-colored cells within 50  $\mu$ m of one another were considered in the same clone. Average number of cells per clone was calculated in addition to the categorical range of distribution for clone size.

### Lung alveolar epithelial cell isolation

Lungs from *Axin2<sup>CreERT2-TdTomato</sup>* pups were harvested at P4 and processed into single cell suspensions using a dispase (Collaborative Biosciences)/collagenase (Life Technologies)/DNase solution. Axin2<sup>+</sup> AT2s were sorted from the single suspension using either a MoFlo Astrios EQ (Beckman Coulter) or FACSJazz (BD Biosciences) flow cytometer with antibody staining for CD31-PECy7 (eBioscience), CD45-PECy7 (eBioscience), and EpCAM-APC (eBioscience). Following negative selection for CD31 and CD45, Axin2 AT2s were positively selected for TdTomato and EpCAM and sorted into a modified MTEC-Plus media (SABM (Lonza) instead of DMEM/F12), called MTECSAGM. The total AT2 population (Sftpc<sup>+</sup> AT2s) was isolated from lungs of P4 *Sftpc<sup>CreERT2</sup>:R26R<sup>EYFP</sup>* pups following induction of recombination on P3. Cells were sorted from single cell suspensions after enzyme digestion and isolated based on EYFP fluorescence. Lung fibroblasts for organoid assays were isolated from adult wild type mice. Briefly, lungs were harvested, digested, and processed into a single cell suspension with subsequent plating on plastic tissue culture dishes. Cells were maintained in DMEM/F12 (Life Technologies) supplemented with 10% FBS and 1X Anti-Anti- (Life Technologies). Following three passages, the highly enriched mesenchymal population was analyzed to be greater than 99% pure mesenchyme as determined by flow cytometry assessment using antibodies for epithelial (EpCAM-APC), endothelial (CD31-PECy7), hematopoietic (CD45-PECy7), and mesenchymal cells (CD140a:Pgfra (eBioscience) and CD140b:Pgfr $\beta$  (eBioscience) (Peng et al., 2015)

### Ex vivo lung alveolar organoid assay

For lung alveolar organoid formation, 5,000 Axin2<sup>+</sup> or Sftpc<sup>+</sup> AT2s were mixed with 50,000 primary lung fibroblasts and centrifuged into cell pellets in microcentrifuge tubes. Pellets were resuspended in a 1:1 mixture of MTEC-SAGM:Matrigel (45  $\mu$ l of modified MTEC-SAGM followed by the addition of 45  $\mu$ l of growth factor-reduced, phenol-free Matrigel (Corning)). The mixture was then aliquoted into 24 well cell culture insert (Falcon)

and allowed to solidify at 37°C. MTEC-SAGM was then placed into each well of the 24-well plate. The use of ligands and chemical antagonists were added to both the insert and well culture media at initial formation of organoids. Wnt3a was used at a concentration of 200 ng/uL. IWP-2 was used at 5 μM. DMSO was used for vehicle treatment. Media with or without treatments were replaced every other day until day 14 where organoids were assayed for total number by manual counts. For self-renewal assays, after 14 days organoids were incubated with dispase (Stem Cell Technology) for 30 minutes then incubated in 0.25% Trypsin-EDTA for 30 minutes. Single cell suspensions were obtained, and the cells were re-sorted to regenerate organoids.

### Flow cytometry for expression of *Sftpc* and *Pdpn* in *Axin2+* cells

Cells obtained by FACS from the *Axin2<sup>CreERT2-TdTomato</sup>* lungs were subjected to further analysis for expression of *Sftpc* and *Pdpn*. Cells were first stained with the extracellular *Pdpn* antibody (*Pdpn*-eFluor660, eBioscience, 1:100) followed by fixation and permeabilization using a standard intracellular staining kit (eBioscience). Cells were stained with anti-*Sftpc* primary antibody (goat, Santa Cruz, 1:50) or its goat IgG isotype control both followed by Alexa Fluor 488 secondary antibody. Cells were assessed using flow cytometer (Accuri C6) and results were expressed at percentage of *Axin2+* *EpCAM+* cells.

### Transcriptome Analysis

Comparison of the transcriptomes of P4 *Axin2<sup>CreERT2-TdTomato</sup>* and *Sftpc<sup>CreERT2</sup>:R26<sup>R</sup>EYFP* pups was performed using microarray analysis. FACS-based isolation of AT2 or AT2<sup>*Axin2*</sup> cells from the lungs of five pups for each genotype was performed as described above. Cells were collected in RNAProtect Cell Reagent (Qiagen) and subjected to RNA extraction using a combined Trizol (Life Technologies) and RNEasy MiniElute Cleanup Kit (Qiagen). Biotinylated cRNA probe libraries were constructed and then hybridized to Affymatrix Mouse Gene 2.0ST arrays. Microarray data were analyzed using the Oligo package available at the Bioconductor Web site (<http://www.bioconductor.org>). The raw data were background-corrected by the robust multichip average (RMA) method and then normalized by an invariant set method. Genes with 80% of samples with an expression signal above the negative control probes were considered detectable or present. Differential gene expression analysis was performed using the limma package available at the Bioconductor Web site. P-values were adjusted for multiple comparisons using a false discovery rate. Principal component analysis was performed in R using the *prcomp* function. Gene Ontology enrichment analysis was performed using the ToppFun tool available from the ToppGene suite website (<https://toppgene.cchmc.org>). The Gene Expression Omnibus accession number for the microarray data is GSE82154.

### Statistical Analysis

Statistical analysis was performed on the data using Excel and R. Two-tailed student t-test was used for comparison of two experimental groups. Using the R, a Fishers' exact test was performed to determine an association between clone size and genotype/treatment in all experiments. Statistical data was considered significant if  $P < 0.05$ .

## ACKNOWLEDGEMENTS

The authors are grateful for the technical support of the Penn Cardiovascular Institute Histology Core for histology and immunohistochemical services. In addition, they would like to extend thanks to Andrea Stoudt for confocal microscopy technical support. Support for these studies come from grants from the NIH to E.E.M. (HL087825, HL100405, HL110942), D.B.F. (NIH T32 HL007915 and K12 HD043245), and T.P. (NIH K08 HL121146). In addition, D.B.F. is supported by a fellowship award from the Parker B. Francis Fellowship Program and a grant from the Pulmonary Hypertension Association's Matthew & Michael Wojciechowski Pediatric PH Research & Mentoring Grant.

### Figure 1. A novel reporter mouse defines Wnt-responsiveness in the developing lung

(A and B) The *Axin2<sup>CreERT2-TdTom</sup>* allele produces TdTomato expression in Wnt-responsive (Axin2+) cells located in the mesenchyme and proximal and distal Nkx2.1+ epithelium (A) during branching morphogenesis with (B) showing the same image with RFP and DAPI staining only. Dashed white lines outline distal and solid lines outline proximal airways, respectively. (C) Induction of recombination at E10.5 in *Axin2<sup>CreERT2-TdTom</sup>;*R26<sup>REYFP</sup>** mice followed by a four-day chase demonstrates that Axin2+ cells give rise to both proximal and distal Nkx2.1+ lung epithelium, with a larger number of cells labeled in the distal region

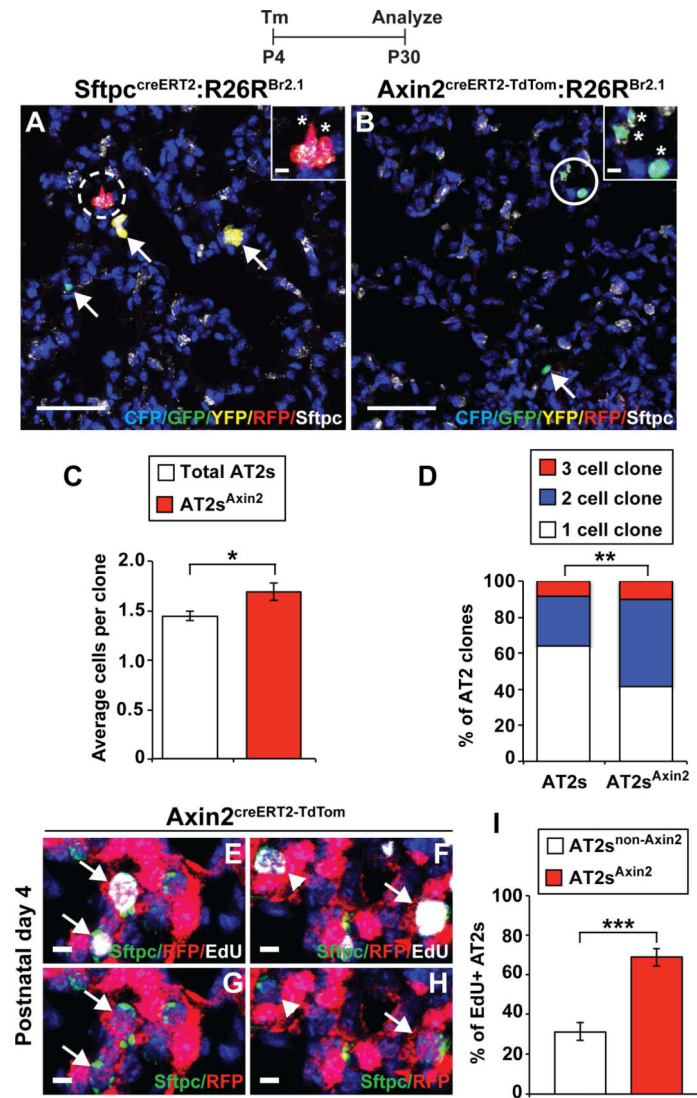

(yellow bracket). (D and E) From E15.5-E16.5, lineage labeled Axin2<sup>+</sup> cells become restricted to distal Sox2<sup>-</sup> (D), Sox9<sup>+</sup> (E) lung epithelium. (F-I) At E17.5-E18, Axin2<sup>+</sup> lung epithelial cells are sparsely located throughout distal bronchiolar and alveolar epithelium. Bronchiolar Axin2<sup>+</sup> cells are predominantly Scgb1a1 secretory cells (F) with very rare Tubb4<sup>+</sup> ciliated cells (G). In the alveolar region, there is a small number of Pdpn<sup>+</sup> AT1s (H) and Sftpc<sup>+</sup> AT2s (I). At P4, Axin2<sup>+</sup> secretory (J) and ciliated (K) bronchiolar cells and AT1s (L) become very rare. However, there is a dramatic increase in Axin2<sup>+</sup> AT2 (AT2<sup>Axin2</sup>) alveolar cells (M). (N) Quantification of Axin2<sup>+</sup> secretory (Scgb1a1<sup>+</sup>) and ciliated (Tubb4<sup>+</sup>) bronchiolar epithelium, AT2s (Sftpc<sup>+</sup>), and AT1s (Pdpn<sup>+</sup>) reveals significant changes in lineage specific Axin2<sup>+</sup> Wnt responsive lung epithelium. (O) At E18, a minority of the Axin2<sup>+</sup> Wnt responsive epithelium is Sftpc<sup>+</sup>. However, by P4 more than 97% of the total Axin2<sup>+</sup> epithelium is a sublineage of the total Sftpc<sup>+</sup> AT2 lineage i.e. AT2<sup>Axin2</sup>s. Arrows in F-M indicate examples of a positive cell and insets are higher magnification of Axin2<sup>+</sup> cells. *D*=distal lung endoderm/epithelium, *P*=proximal lung endoderm/epithelium. Quantification of cell numbers represented as mean ± SEM. Two-tailed student's t-test: \**P* < 0.05, n.s = non-significant; n=3 for each group. Scale bars = 50 μm.

**Figure 2. A wave of Wnt signaling occurs in AT2s during alveologensis**

(A) Graphic model illustrates the dynamic changes in Axin2+ Wnt-responsive lung epithelium during lung development. Late lung development is marked by restriction of Axin2+ epithelial cells to the distal alveolus and a significant increase in AT2<sup>Axin2</sup> cells during alveologensis. While there are few AT2<sup>Axin2</sup> cells at E17.5-E18.0 (B and C), their numbers increase significantly by P1 (D and E) and P4 (F and G). AT2<sup>Axin2</sup> cells continue to be observed at P30 (H and I). Dotted lines surround Sftpc+ AT2 and AT2<sup>Axin2</sup> cells in insets C, E, G, I. (J-L) Lineage traced AT2<sup>Axin2</sup> cells from E18.5 to P10 (J) and P4 to P10 (K) show a marked increase in AT2<sup>Axin2</sup> cell expansion between these time points. Arrows indicate positive cells, which are quantified in (L). (M) Total AT2s isolated by FACS following a 24-hour tamoxifen induction. (N) Expression of Axin2 mRNA at P4 compared to E18.5 in AT2s showing a two-fold increase in expression. (O and P) Axin2+ lung epithelial cells are isolated using negative selection for CD31 and CD45 (upper FACS plot) and positive selection for TdTomato and EpCAM (lower FACS plot). (P) By flow cytometry, isolated Axin2+ lung epithelial cells are composed predominantly of AT2s<sup>Axin2</sup> as measured by intracellular Sftpc and extracellular Pdpn staining. Quantification of cell numbers, qPCR data, and cell type percentage represented as mean ± SEM. Two-tailed student's t-test:  $P < 0.05$ ;  $n=3-4$  for each group. Scale bars: B, D, F, H, J, K = 50 μm; C, E, G, I = 10 μm; J, K = 5 μm.

AT2s<sup>Axin2</sup>, n=4 (191 clones) for total AT2s; Two-tailed student's t-test: \*\*\* $P < 0.05$ , n=3 with 10 independent fields of view per mouse. Scale bars: A and B = 50  $\mu\text{m}$ , E-H = 5  $\mu\text{m}$ .

**Figure 4. The AT2<sup>Axin2</sup> sublineage is highly enriched in genes important for alveologenesis** (A) Principal component analysis illustrates unique segregation of the AT2<sup>Axin2</sup> sublineage from the total AT2 population. (B) Microarray analysis comparing the total AT2 population versus the AT2<sup>Axin2</sup> sublineage demonstrates enrichment of up-regulated genes for cell cycle, vascular development, and extracellular matrix interactions and production and down-regulation of genes associated with metabolism and lipid metabolism in the AT2<sup>Axin2</sup> sublineage. (C-L) qPCR analysis on genes important in alveolar growth and differentiation

confirms microarray findings on selected genes. Quantification of qPCR data is represented as mean  $\pm$  SEM. Two-tailed student's t-test: \* $P < 0.05$ , n=4 for each group.

**Figure 5. AT2s<sup>Axin2</sup> exhibit enhanced *ex vivo* lung organoid formation**  
 (A-C) AT2s<sup>Axin2</sup> exhibit an increase in colony forming efficiency for lung alveolar organoid formation compared to total AT2s at passage 0 (P0) and passage 1 (P1). By passage 2 and 3 (P2-P3), these differences are no longer significant. (D and F) Hematoxylin and eosin (H&E) staining showing organoid structure in total AT2s and AT2s<sup>Axin2</sup>. (E and G) Immunohistochemical staining for the AT2 and AT1 markers, Sftpc and Pdpn, respectively, demonstrate that total AT2s and AT2s<sup>Axin2</sup> are composed of both differentiated AT2s and AT1s. (H-L) Wnt3a treatment increases CFE while IWP2 treatment inhibits CFE in AT2

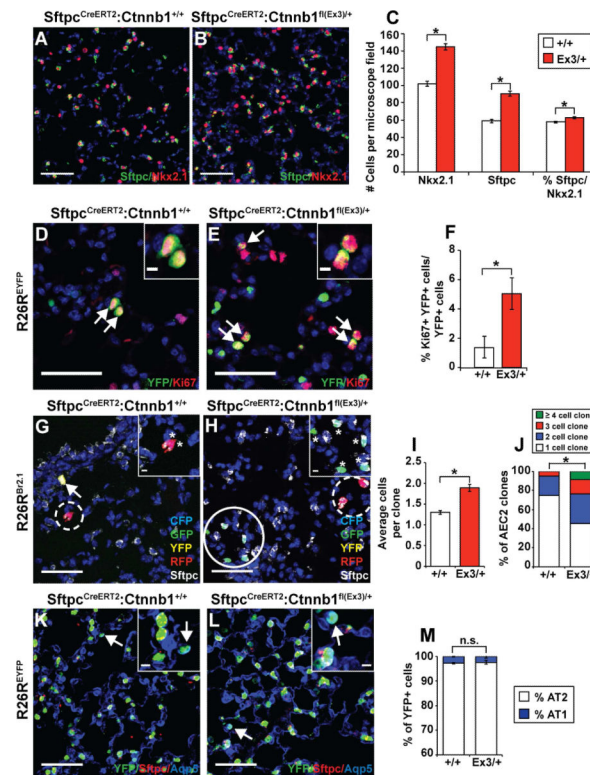

derived organoids. Treatment with both IWP2 and Wnt3a shows that inhibition can be rescued, in part, with exogenous Wnt ligand. Quantification of CFE is represented as average CFE  $\pm$  SEM. Two-tailed student's t-test: \* $P < 0.05$ ,  $n > 3$  for each group in 4 independent experiments for A-I,  $n > 2$  for each group in 3 independent experiments for J-N.

**Figure 6. Wnt activation increases AT2 proliferation and expansion during alveologenesis *in vivo*** (A-C) Activation of Wnt signaling increases total alveolar epithelial cell and AT2 cell numbers when lineage tracing from P4 to P30 compared to  $Sftpc^{CreERT2};Cttnb1^{+/+}$  control mice. Both total Nkx2.1+ and Sftpc+ cells are increased in the alveolar region. (D-F) Proliferation as measured by Ki67 staining is increased in  $Sftpc^{CreERT2};Cttnb1^{fl(Ex3)/+}$  mutants compared to controls. Arrows indicate Ki67+ Sftpc lineage marked cells. (G-J) Wnt activation in AT2s results in clonal expansion of AT2s as noted by increased cell number per clone and increased clone size. Note the larger size of the CFP clone in H as compared to the YFP and RFP clones in G. (K-M) AT1 cell differentiation is unaffected by activation of Wnt signaling in AT2s as noted by co-staining for the YFP lineage mark and Aqp5. Quantification of cell number counts, % Ki67+, average clone size, and % of YFP+ cells is represented as mean  $\pm$  SEM. Two-tailed student's t-test: \* $P < 0.05$ ,  $n > 4$  for each group; Two-tailed student's t-test: \*\* $P < 0.05$  and Fisher's exact test: \*\*\* $P < 0.05$ ,  $n = 142$  clones for  $Sftpc^{CreERT2};Cttnb1^{+/+}$  and  $n = 258$  clones for  $Sftpc^{CreERT2};Cttnb1^{fl(Ex3)/+}$  mutants.

**Figure 7. Loss of Wnt signaling in AT2s inhibits proliferation and promotes differentiation into AT1s**

(A-C) Proliferation is reduced in *Sftpc<sup>CreERT2</sup>:Ctnnb1<sup>fl/fl</sup>* mutant AT2s compared to controls following deletion of  $\beta$ -catenin from P4 to P30. (D-F) Loss of Wnt signaling in *Sftpc<sup>CreERT2</sup>:Ctnnb1<sup>fl/fl</sup>;R26R<sup>Br2.1</sup>* mutants from P4 to P30 leads to increased differentiation into AT1s during alveologenesis as noted by the increase in clones exhibiting the spread and flattened morphology of AT1 cells. (G-I) These data were confirmed using the *R26R<sup>mTmG</sup>* reporter to outline the cell surface of the AT1 cells along with Aqp5 co-immunostaining. (J) Illustration depicting the role of re-emergent Wnt signaling in balancing epithelial growth

and differentiation during lung alveologenesis. Quantification of % Ki67+, average % of clone, and % of YFP+ cells is represented by mean  $\pm$  SEM. Two-tailed student's t-test: \* $P < 0.05$ ,  $n > 4$  for each group; Two-tailed student's t-test: \*\* $P < 0.05$ ,  $n=133$  clones for controls and  $n=203$  clones for *Sftpc*<sup>CreERT2</sup>:*Ctnnb1*<sup>f1/f1</sup> mutants.
