### Abstract

**Background**—Patient comprehension is fundamental to valid informed consent. Current practices often result in inadequate patient comprehension.

**Purpose**—An updated review to evaluate the characteristics and outcomes of interventions to improve patient comprehension in clinical informed consent.

**Data sources**—Systematic searches of MEDLINE and EMBASE (2008-2018).

**Study Selection**—We included randomized and non-randomized controlled trials evaluating interventions to improve patient comprehension in clinical informed consent.

**Data Extraction**—Reviewers independently abstracted data using a standardized form, comparing all results and resolving disagreements by consensus.

**Data Synthesis**—Fifty-two studies of 60 interventions met inclusion criteria. Compared to standard informed consent, a statistically significant improvement in patient comprehension was seen with 43% (6/14) of written interventions, 56% (15/27) of audiovisual interventions, 67%

Corresponding author: Johanna Glaser, UCSF Osher Center for Integrative Medicine, 1545 Divisadero St, Room 515, San Francisco, CA 94115, Phone: (510) 332-1444, johanna.glaser@ucsf.edu.

(2/3) of multicomponent interventions, 85% (11/13) of interactive digital interventions, and 100% (3/3) of verbal discussion with test/feedback or teach-back interventions. Eighty-five percent of studies (44/52) evaluated patients' understanding of risks, 69% (41/52) general knowledge about the procedure, 35% (18/52) understanding of benefits, and 31% (16/52) understanding of alternatives. Participants' education level was reported heterogeneously, and only 8% (4/52) of studies examined effects according to health literacy. The majority of studies (79%, 41/52) did not specify participants' race/ethnicity.

**Limitations**—Variation in interventions and outcome measures precluded conduct of a meta-analysis or calculation of mean effect size. Control group processes were variable and inconsistently characterized. Nearly half of studies (44%, 23/52) had high risk of bias for the patient comprehension outcome.

**Conclusions**—Interventions to improve patient comprehension in informed consent are heterogeneous. Interactive interventions, particularly with test/feedback or teach-back components, appear superior. Future research should emphasize all key elements of informed consent and explore effects among vulnerable populations.

## INTRODUCTION

Clinical informed consent is ethically and legally required prior to invasive medical and surgical procedures. Informed consent occurs when patient-clinician communication results in a patient's authorization to undergo a specific medical intervention.<sup>1</sup> This authorization is only valid if the patient has the capacity to consent, has discussed and understood all relevant information, consents voluntarily, and communicates their decision.<sup>2</sup> Relevant information encompasses four key elements of informed consent: risks, benefits, alternatives, and general knowledge about the procedure.<sup>3, 4</sup>

Standard informed consent generally consists of a patient-clinician discussion followed by the signing of an informed consent document, though specific methods vary. Such practices commonly result in inadequate patient comprehension.<sup>3, 5-8</sup> Lack of adequate understanding is particularly common for vulnerable populations such as those who face language barriers or those with limited education or health literacy.<sup>8-13</sup> Current practices also generally fail to define adequate patient comprehension and to ensure its assessment as part of the informed consent process.

Internationally, standards of informed consent practice continue to evolve. Explicit protection from non-consensual medical treatments and procedures have long been upheld by international law, though actual practices of informed consent vary by country and may be influenced by cultural context.<sup>14-20</sup> Overall, there has been a trend toward more patient-centered informed consent standards in recent years.<sup>21-23</sup> There are not, however, international ethical guidelines for clinical informed consent similar to those that have been developed to regulate human subject research.<sup>24,25</sup>

We previously conducted a systematic review evaluating studies published between 1949 and 2008 of interventions to improve patient comprehension in informed consent for medical and surgical procedures.<sup>26</sup> Most included studies (26/44) were fair or poor quality.

We found that most interventions resulted in improved patient comprehension compared to standard informed consent, without demonstrable superiority of any particular intervention type. We also found that studies overwhelmingly focused on patient understanding of risks over other key elements of informed consent, suggesting the prioritization of malpractice risk reduction over enhancement of patient autonomy.

This systematic review is an update of our prior report. Since 2008, many relevant studies have been published, including trials evaluating novel interactive digital interventions to improve patient comprehension in informed consent. Additionally, standards for evaluating bias in systematic reviews have evolved to better safeguard against the perpetuation of misleading or biased data within primary studies.<sup>27-29</sup> In this review, we sought to evaluate the characteristics (i.e. procedure type, intervention characteristics, comprehension measures, study country, and study population), risk of bias, and outcomes of the recent evidence base for improving patient comprehension in clinical informed consent. As a secondary aim, we assessed the degree to which relevant studies addressed vulnerable populations.

## METHODS

We conducted a systematic review of interventions to improve patient comprehension in clinical informed consent. We registered our protocol (PROSPERO ID: CRD42019118264) prior to screening search results and adhered to the study plan therein. This study was exempt from IRB approval.

### Study Eligibility

Inclusion criteria included English-language randomized controlled trials (RCTs) and non-randomized controlled trials (NRCTs) that compared the level of comprehension among patients who underwent standard informed consent with those who underwent an enhanced informed consent process for a necessary or recommended clinical procedure or surgery. We considered standard informed consent to include institution-specific standard consent processes and standardized versions of these processes as designed for individual studies (e.g., the use of a checklist to ensure discussion of key points). We selected only studies that utilized a quantitative, objective measure of patient comprehension. We excluded studies described as pilot, feasibility, and exploratory trials, as well as studies evaluating informed consent for research, screening tests, biobanking, genetic testing, advance directives, psychotherapy, and prescription drugs. We also excluded trials in which informed consent was obtained from surrogates, and studies evaluating decision aids designed to help patients choose between various medical management options (i.e. multiple reasonable procedures or medical versus surgical management options for a given medical condition). Interventions that utilized decision aids to enhance patient education in informed consent for a necessary or medically recommended procedure were included.

### Study Identification

We conducted a systematic search of MEDLINE (PubMed interface from September 2008 to November 2018) and EMBASE (Elsevier interface from September 2008 to November

2018). A senior reference librarian (M.K.F.) designed the search strategy (Appendix 1). We included search terms aimed to identify interventions designed for vulnerable patient populations such as “English proficiency,” “limited literacy,” and “health literacy.” We examined the reference lists of selected studies identified in the search to enhance the likelihood that all relevant articles were captured.

### Study Selection

One reviewer (J.G) screened the initial set of articles by title and abstract. We retrieved all articles identified as potentially relevant in full text. Two reviewers (J.G. and S.N.) performed a full-text review of these articles, comparing inclusion and exclusion results. Discrepancies were resolved by consensus with the senior author (Y.S.).

### Data Extraction and Synthesis

Three members of the study team (J.G, S.N, Y.S.) developed a standardized data abstraction form (Appendix 2). Two reviewers (J.G. and S.N.) then independently abstracted data from each study, resolving discrepancies with the senior author (Y.S.).

**Study design**—All studies were described as RCTs. However, we determined that some employed non-random allocation methods, and reclassified them as NRCTs.

**Types of interventions**—We grouped interventions into five categories. (1) *Written interventions* included written materials providing information in addition to standard informed consent as well as simplified versions of standard consent documents. Written interventions could contain limited graphics as long as visual components were not the primary information delivery method. (2) *Audiovisual interventions* included posters, non-interactive digital images, videos, 3-dimensional models, and audio and video-recordings. Audiovisual interventions could contain limited text as long as written components were not the primary information delivery method. (3) *Interactive digital interventions* included computer, electronic tablet, and phone applications with interactive features. (4) *Verbal discussion with test/feedback or teach-back interventions* included interventions in which participants completed an informed consent discussion with a clinician, were tested for comprehension, and then given repeated or further verbal information based on their understanding. (5) *Multicomponent interventions* included interventions with components spanning two or more of the previous categories for a single study group.

Across all categories, we also grouped interventions according to whether they were *interactive* or *noninteractive*. *Interactive interventions* included those specifically designed to promote active patient involvement and bi-directional communication, such as patients’ physical interaction with 3-dimensional anatomical model during the consent discussion and digital interventions that allowed patients to navigate through educational modules. We further classified interactive interventions by whether they included test/feedback or teach-back components (i.e. explicit communication prompts to assess comprehension of elements of informed consent domains). *Noninteractive interventions* could include discussion with the consenting clinician but no other interactive features requiring active patient participation.

**Study populations**—We abstracted the inclusion and exclusion criteria of primary studies as well as study participants' age, race/ethnicity, proficiency in the study language, educational attainment, and health literacy and numeracy. We additionally abstracted data on the reading level of intervention materials and all sub-analyses conducted on the basis of sociodemographic factors

**Outcome measures**—Our primary outcome was the difference in patient comprehension scores between study groups. We recorded elements of patient comprehension assessed (risks, benefits, alternatives, and general knowledge about the procedure) and timing of the patient comprehension measure (categorized as *immediate* (within 1 hour of consent consultation), *early* (<24 hours but >1 hour after consent consultation) or *delayed* (>24 hours after consent consultation) to broadly reflect working memory, short-term memory, and long-term memory).<sup>30</sup> We also recorded study setting, amount of provider time required to obtain informed consent, patient satisfaction with the informed consent process, and patient anxiety. We only considered an intervention to have resulted in improved patient comprehension if the results were statistically significant.

**Risk of bias**—We assessed bias using the Cochrane risk-of-bias 2 (RoB 2.0) tool<sup>31-33</sup> for the patient comprehension outcome in each trial, including those we reclassified as NRCTs due to use of non-random allocation methods. This tool can be utilized to assign 'low risk,' 'some concerns,' or 'high risk' of bias per study outcome. Overall risk-of-bias judgments are based on assessments in 5 domains. Two reviewers (J.G and S.N.) independently assessed all studies in this manner and resolved any discrepancies.

## RESULTS

### Literature Search

The literature search yielded 2157 citations; 1850 remained after removing duplicates. Initial screening yielded 75 full-text articles, of which 52 studies evaluating 60 interventions were ultimately included (Figure 1).

### Study and Participant Characteristics

Studies were conducted in 18 countries (Tables 1-6). Most were RCTs; three were NRCTs.<sup>34-36</sup> The majority (41/52) addressed informed consent for surgical procedures, 9 for medical procedures, and 2 for a mixture of medical and surgical procedures. Seven studies specified that interventions took place in the outpatient setting,<sup>37-43</sup> six in the inpatient setting,<sup>44-49</sup> and one in the emergency department.<sup>50</sup> The remaining 38 studies did not specify setting.

All studies included control groups that received standard informed consent, though few provided full details of the standard informed consent process (Tables 1-6). When described, standard informed consent generally consisted of a patient-clinician discussion followed by the signing of an institution-specific informed consent form, and sometimes included the provision of standardized written educational materials.

Type and quantity of participant sociodemographic information varied widely. Mean patient age ranged from 22.4 to 74 years old (Tables 1-6). The majority of studies did not specify participants' health literacy level (88%, 46/52) or race/ethnicity (79%, 41/52) and four studies explicitly excluded participants with low literacy levels.<sup>38,51-53</sup> Twenty-four studies (46%) included proficiency in the study language in their eligibility criteria, and only 3 specified inclusion of participants requiring interpreters.<sup>37, 54, 55</sup> Education was reported in a variety of ways, including percent of participants having completed certain school levels, or mean education in years (Tables 1-6). Of 29 studies that reported education in a way that could be categorized as "high school or less," 22 included 30% of participants with this level of education.

### Variations in Patient Comprehension Measures

Patient comprehension measures ranged from true/false, multiple choice, and open-ended questionnaires to semi-structured interviews (Tables 1-6). The majority (81%, 42/52) were neither validated nor adapted from a validated measure.

Key elements of informed consent assessed by patient comprehension measures varied by study (Tables 1-6). Evaluation of patient understanding of risks was most common (85% of studies, 44/52) followed by general knowledge about the procedure (69%, 41/52), benefits (35%, 18/52) and alternatives (31%, 16/52). Eleven studies (21%) assessed all four key elements of informed consent.<sup>36, 51, 56-64</sup> Five studies (10%) did not specify which elements of patient comprehension were assessed.<sup>39, 42, 45, 52, 65</sup>

Twenty-two studies (41%) evaluated immediate patient comprehension, 5 (10%) evaluated early patient comprehension, 23 (44%) evaluated delayed patient comprehension, and 11 (21%) did not specify timing (Tables 1-6).

### Effect of Interventions on Patient Comprehension

**Written interventions**—Thirteen studies evaluated 14 written interventions (Tables 1 and 6).<sup>38, 44, 45, 49, 54, 60, 66-72</sup> Written interventions ranged from simplified, single-page handouts to multiple-page pamphlets. Six written interventions (43%) resulted in improved patient comprehension compared to standard informed consent (Figure 2)<sup>45, 49, 60, 66, 69, 71</sup> and 8 did not<sup>38, 44, 54, 60, 67, 68, 70, 72</sup> Fifty percent (2/4) of written intervention trials with some bias risk resulted in improved patient comprehension<sup>66, 71</sup> compared with 40% (4/10) of those with high bias risk.<sup>45, 49, 69</sup> Ten interventions provided written information in addition to standard informed consent<sup>45, 49, 54, 60, 66, 69-72</sup> of which six (60%) improved patient comprehension; four provided written information in place of standard informed consent,<sup>38, 44, 67, 68</sup> none of which resulted in improved patient comprehension. Four written interventions indicated reading level, which ranged from 2<sup>nd</sup> to 8<sup>th</sup> grade.<sup>38, 60, 72</sup> Only the intervention written at a 2<sup>nd</sup> grade reading level resulted in improved patient comprehension compared to the control group.<sup>60</sup> No written interventions contained interactive, test/feedback, or teach-back components.

**Audiovisual interventions**—Twenty-five studies evaluated 27 audiovisual interventions (Tables 2 and 6).<sup>34, 36, 37, 39, 40, 42, 43, 46, 48, 50, 60, 63, 64, 65, 68, 73-82</sup> Audiovisual interventions

Author Manuscript  
Author Manuscript  
Author Manuscript  
Author Manuscript

included videos of varying length, visual aids (non-interactive Powerpoint or multimedia presentations, posters, diagrams, or anatomical models), and audio and video-recordings. Fifteen audiovisual interventions (56%) resulted in improved patient comprehension compared to standard informed consent (Figure 2)<sup>34, 39, 40, 42, 48, 50, 60, 65, 75, 78-81</sup> and the remaining did not. Fifty-three percent (9/17) of audiovisual intervention trials with some bias risk resulted in improved patient comprehension<sup>39, 39, 42, 48, 50, 79, 75, 80</sup> compared with 60% (6/10) of those with high bias risk.<sup>34, 40, 60, 65, 78, 81</sup> Seventeen studies utilized audiovisual interventions in addition to standard informed consent,<sup>34, 36, 37, 39, 40, 48, 50, 60, 63, 64, 74, 75, 78-82</sup> of which 11 (65%) resulted in improved patient comprehension compared to control. Four studies assessed audiovisual interventions in place of standard informed consent,<sup>46, 65, 68, 76</sup> of which 1 (25%) resulted in improved patient comprehension compared to control. One audiovisual intervention was interactive: participants held and touched specified aspects of an anatomical model during the consent discussion.<sup>39</sup> No audiovisual interventions contained test/feedback or teach-back components.

**Interactive digital interventions**—Thirteen studies evaluated 13 interactive digital interventions (Tables 3 and 6), including computer, electronic tablet, and mobile phone applications that had features requiring active patient participation. The majority of interactive digital interventions (85%, 11/13) resulted in improved patient comprehension compared to standard informed consent (Figure 2).<sup>38, 41, 51, 52, 55, 58, 61, 62, 83-85</sup> Six used computer-based programs, 4 used tablet applications, 2 used web modules, and one used a mobile phone application. Eighty-six percent (6/7) of interactive digital intervention trials with some bias risk resulted in improved patient comprehension<sup>51, 52, 55, 61, 62, 85</sup> compared with 83% (5/6) of those with high bias risk.<sup>38, 41, 58, 83, 84</sup> Nine were provided in addition to standard informed consent,<sup>41, 51-53, 55, 83-85</sup> of which seven (78%) resulted in improved patient comprehension; two were provided in place of standard informed consent, both of which resulted in improved patient comprehension,<sup>61, 62</sup> and one study did not specify.<sup>58</sup> All of the interactive digital interventions contained interactive features and 5 included a test/feedback component.<sup>52, 58, 61, 62, 84</sup>

**Verbal discussion with test/feedback or teach-back interventions**—Three studies evaluated 3 verbal discussion with test/feedback or teach-back interventions (Tables 4 and 6).<sup>34, 57, 59</sup> In one intervention, patients received routine preoperative education followed by a knowledge test. They then received a corrected copy of their test followed by a telephone call with a nurse who reviewed the test and provided additional information tailored to their level of understanding.<sup>59</sup> In the other two interventions, patients underwent standard informed consent and were then prompted to teach back key information to the consenting physician.<sup>34, 57</sup> All of the verbal discussion with test/feedback or teach-back interventions (3/3, 100%) resulted in improved patient comprehension compared to standard informed consent. Two of these trials had some bias risk<sup>57, 59</sup> and one had high bias risk.<sup>34</sup>

**Multicomponent interventions**—Three studies evaluated 3 multicomponent interventions (Tables 5 and 6).<sup>35, 36, 47</sup> One utilized a paper-based decision aid written at an 8<sup>th</sup> grade reading level plus access to a website with supplemental videos,<sup>47</sup> one provided a

written pamphlet and showed patients an anatomical model during the consent discussion (no patient interaction with the model was described)<sup>35</sup>, and one provided an educational video plus an additional education session with a nurse coordinator/educator (further details were not provided).<sup>36</sup> The first two (67%) resulted in improved patient comprehension. Of these, one had some risk of bias<sup>47</sup> and one had high risk of bias.<sup>78</sup> The third did not result in improved patient comprehension. This intervention had high risk of bias.<sup>36</sup> All multicomponent interventions were provided in addition to rather than in place of standard informed consent; none contained interactive, test/feedback, or teach-back components.

**Interactive versus Noninteractive Interventions**—Across the above categories, a total of 43 interventions (72%) were noninteractive and 17 (28%) were interactive. Eight of the interactive interventions included test/feedback or teach-back components including one audiovisual intervention,<sup>39</sup> 5 digital interventions<sup>52, 58, 61, 62, 84</sup> and 3 verbal discussion with test/feedback or teach-back interventions.<sup>34, 57, 59</sup> Fifty-three percent (23/43) of noninteractive interventions, 78% (7/9) of interactive interventions without test/feedback or teach-back components, and 100% (8/8) of interactive interventions with test/feedback or teach-back components resulted in improved patient comprehension compared to standard informed consent (Figure 3).

**Timing of Comprehension Measures**—In general, improvements in patient comprehension were more pronounced on immediate testing, though two studies found improvements on early testing<sup>35, 78</sup> and fourteen studies found improvements on delayed testing.<sup>40, 41, 47, 49, 52, 59, 66, 69, 79, 81, 61, 62, 83, 84</sup>

### **Effect of Interventions on Other Outcomes**

Twenty-seven studies evaluated patient satisfaction with the informed consent process. Eight (30%) demonstrated higher satisfaction among the intervention group compared to standard informed consent<sup>46, 48, 50, 51, 64, 71, 75, 77</sup> and 19 (70%) found no difference in satisfaction between groups.

Fourteen studies evaluated patient anxiety. Twelve (86%) found no difference in anxiety between intervention and control groups,<sup>34, 38, 40, 48, 51, 57, 65, 68, 74, 77, 80, 82</sup> and 2 (14%) found less anxiety among intervention group patients.<sup>42, 76</sup>

Ten studies evaluated amount of provider time required to obtain informed consent. Two found no difference in the intervention group compared to standard informed consent.<sup>54, 77</sup> Five interventions reduced consultation time with the consenting provider by an average of 4–6.7 minutes.<sup>63, 64, 68, 74, 79</sup> One intervention with reduced consultation time resulted in improved patient comprehension.<sup>79</sup> Three verbal discussion with test-feedback or teach-back interventions required longer consultation times, by an average of 2.3, 2.6, and 21 minutes, and each resulted in improved patient comprehension compared to standard informed consent.<sup>34, 57, 59</sup>

## Informed Consent and Vulnerable Populations

Some studies conducted sub-analyses on the basis of sociodemographic data, most commonly examining education (19 studies), age (16 studies), and gender (12 studies). Lower education (10/19 studies), older age (6/16 studies), and limited health literacy (3/4 studies) were associated with lower patient comprehension scores; however, these studies did not clearly specify whether interventions were differentially effective based on these factors. Only four studies examined effects according to health literacy<sup>52, 57, 61, 62</sup> of which one reported a statistically significant improvement in comprehension scores among participants with limited health literacy receiving the intervention.<sup>52</sup> Reading level of intervention materials was reported in seven studies, and ranged from 2<sup>nd</sup> to 8<sup>th</sup> grade.<sup>30, 47, 51, 58, 60, 72, 84</sup> One study assessed the efficacy of an informed consent intervention for patients with language barriers, finding that non-native speakers of the study language showed decreased comprehension compared to native speakers in both the control and intervention groups.<sup>37</sup>

## Risk of Bias

No study had a low overall bias risk for the patient comprehension outcome; 56% (29/52) had some concerns and 44% (23/52) had high overall risk (Appendix 3). Factors that most commonly increased risk of bias were non-blinding of study participants, those delivering the intervention, or outcome assessors, lack of allocation concealment, data availability for <90% of participants randomized, and lack of a pre-specified trial registration or protocol.

## DISCUSSION

In this systematic review, we identified 52 studies evaluating 60 interventions to improve patient comprehension in informed consent for medical and surgical procedures published between 2008 and 2018. Studies included written, audiovisual, interactive digital, verbal discussion with test/feedback or teach-back, and multicomponent interventions. Overall, about two thirds of interventions improved patient comprehension. A higher proportion of verbal discussion with test/feedback or teach-back and interactive digital interventions improved patient comprehension than did multicomponent, audiovisual, or written interventions. Effective interventions could be delivered without placing undue time burdens on providers or negatively impacting patient satisfaction or anxiety, though less than a third of studies reported the impact of interventions on time required of providers or on patient anxiety. Our results show that a variety of interventions may be helpful in improving patient comprehension in clinical informed consent.

Our findings suggest, however, that interactive informed consent interventions, i.e. those that intentionally promote active patient involvement and bi-directional communication, may be superior to noninteractive interventions. Among interactive interventions, those that utilize test/feedback and teach-back techniques appear particularly effective. This finding is in accordance with previous literature,<sup>12, 86</sup> and multiple organizations already include teach-back recommendations in their quality guidelines for clinical informed consent.<sup>21, 87, 88</sup> Non-interactive interventions, such as those in which patients independently read additional information or reviewed visual aids, were less likely to improve patient comprehension.

Non-interactive interventions provided in place of rather than in addition to standard informed consent appeared to be the least affective. Interactive digital interventions may promote improved patient comprehension regardless of whether they are provided in place of or in addition to standard informed consent. These interventions could potentially be developed to meet quality standards, though additional studies assessing dissemination and implementation are needed. Additionally, interactive digital interventions can help ensure efficiency of clinician-patient informed consent discussions by allowing patients to independently navigate through digital information, gaining understanding and recording questions prior to clinician involvement.

As in our original review, the most commonly assessed element of patient comprehension was understanding of procedural risks, with fewer studies evaluating patients' understanding of benefits, alternatives, and general knowledge about the procedure. Only about a fifth of studies evaluated understanding of all four elements. This suggests a continued emphasis on malpractice risk reduction over patient autonomy and the use of informed consent in a physician-centered rather than a patient-centered manner. Future studies examining efficacy of informed consent interventions should equally emphasize and assess understanding of all four key elements of informed consent.

Sociodemographic information provided by studies addressing language proficiency, education, and health literacy was sparse and highly variable. The majority of studies did not explicitly address effectiveness of interventions for patients representing vulnerable populations, for whom current informed consent practices are particularly inadequate. This represents an important gap in current research.

The majority of tools used to assess patient comprehension were neither validated nor adapted from validated measures. This reflects a lack of standards defining adequate patient comprehension in informed consent and of practices ensuring that adequate patient comprehension is achieved.

We recommend further research addressing patient comprehension in informed consent for vulnerable populations. Specific quality standards for informed consent should be developed, including 1) defining adequate patient comprehension encompassing all four key elements of informed consent, 2) developing validated measures to assess attainment of adequate patient comprehension within routine informed consent, 3) consistently using easy-to-understand, linguistically and culturally appropriate materials to specifically ensure adequate comprehension for patients facing language barriers and for patients with limited education and health literacy, and 4) including interactive components within the informed consent process, particularly test/feedback and teach-back techniques.

Our study has limitations. First, the accuracy of our findings is limited by the quality of included studies; none achieved a low overall risk-of-bias assessment for the patient comprehension outcome. This, however, is likely the result of increasingly rigorous standards for risk-of-bias evaluations in systematic reviews, which have evolved to better safeguard against the perpetuation of bias in primary studies. Additionally, results from studies within our review with lower risk for bias showed a similar pattern of benefit

Author Manuscript  
Author Manuscript  
Author Manuscript  
Author Manuscript

compared to results from all included studies. Second, wide variation in patient comprehension assessment tools and reporting precluded conduct of a meta-analysis or calculation of mean effect size. We were therefore unable to compare the magnitude of effects by intervention type or other factors. Developing and validating standardized patient comprehension measures is an important area of future research to enable comparisons of this type. Third, standard informed consent for control groups was inconsistent across studies and often not clearly described, making it difficult to determine the exact processes to which interventions were compared. Fourth, although some included studies conducted sub-analyses on the basis of sociodemographic factors, there was not sufficient data to draw meaningful conclusions about whether interventions provided equal benefit to vulnerable populations. Fifth, our review may be biased by exclusion of non-English language studies, though study countries were relatively diverse. Finally, our review may be subject to publication bias, though about a third of evaluated interventions had negative findings.

In summary, we found evidence of the efficacy of a variety of interventions to improve patient comprehension in informed consent for medical and surgical procedures. Interactive features appear especially helpful in improving patient understanding, particularly those incorporating test/feedback and teach-back components. Novel interactive digital interventions are particularly promising. Further research should better address vulnerable populations to ensure that interventions equally benefit patients facing language barriers and those with limited education and health literacy.

**Figure 1.**

Results of literature searches to identify studies of interventions to improve patient comprehension in clinical informed consent

**Figure 2:**  
Number of Interventions that Improved or Did Not Improve Patient Comprehension in Informed Consent by Intervention Type

**Figure 3.**

Percent of Interventions that Improved Patient Comprehension in Informed Consent by Degree of Interactivity

**Table 1.**

Results from trials of written interventions to improve patient comprehension in informed consent

Source	Study country	N	Mean patient age (and range if specified)	Patients' education	Procedure	Intervention	Comprehension assessment tool	Timing of patient comprehension relative to informed consent*	Risk of bias for patient comprehension outcome†	Results	Group favored‡
Sternsle et al. (2011)	Switzerland	185	54 y	26% primary education, 37% apprenticeship, 26% secondary education, 12% university	Elective orthopedic surgery	Information form describing types of anesthesia pre-operative instructions, recovery, and the role of the anesthetist (testing in 20 patients for understanding, legibility, and completeness, reading level not specified) given to patients before the pre-anesthetic consultation versus standard care (control)	General knowledge about procedure	Immediately	Some concerns for bias	Percentage of correct answers 75% intervention vs. 62% control, P < 0.01	Intervention
Borello et al. (2016)	Italy	70	Mean age not specified, range 24–80 y	50% did not complete high school, 26% completed high school, 23% college with some graduate school	Laparoscopic cholecystectomy	Standard verbal explanation using a simplified informed consent document with bulleted text and limited anatomical images (reading level not specified) in place of a standard informed consent document versus standard verbal explanation using "standard text document" (control)	Risks, general knowledge about procedure	9-item multiple choice questionnaire	Not specified	Some concerns for bias	Neither
Wong et al. (2016)	Canada	60	55.8 y	20% did not complete high school, 27% completed high school, 49% with some college or trade school, 4% with some graduate school	Carpal tunnel release surgery	Single-sided, single page pamphlet detailing risks at a 7th grade reading level provided following standardized informed consent consultation (detailed, standardized discussion of potential complications) versus standard informed consent consultation alone (control)	Risks	Blinded research team member used standardized script to ask patients to recall risks via telephone	Delayed	Some concerns for bias	Neither
Armeni et al. (2011)	Nigeria	50	43.9 y (range 16–76)	52% high school or less, 48% some degree of postsecondary training	Mastrectomy, tamponoplasty, nasal polypectomy, rhinotomy, and, laryngoscopy	Information handout addressing risks of the specific procedure (reading level not specified) in addition to verbal consent using a standard checklist of risks versus verbal consent using a standard check-list of risks only (control)	Risks	Telephone interview assessing recall of risks discussed	Delayed	Some concerns for bias	Neither
Finch et al. (2009)	England	100	73.5 y	Not specified	Transurethral resection of the prostate	Informed consent using British Association of Urological Surgeons (BAUS) procedure-specific consent form including check boxes for frequently occurring risks (reading level not specified) versus informed consent using conventional Department of Health Type 1 consent form (control)	Risks, benefits, general knowledge about procedure	"Short, standardized questionnaire"	Early	High risk of bias	Neither
Hong et al. (2009)	Canada	100	42.7 (range 20–68)	60% no university, 40% university or higher	Rhinoplasty	Written pamphlet outlining the risks of the procedure (reading level not specified) in addition to oral dialogue with surgeons using a checklist of complications versus oral dialogue alone (control)	Risks	Recall of risks via telephone call with guided questions answers recorded* on a standard set form*	Delayed	High risk of bias	Intervention
Khan et al. (2013)	England	114	Not specified	Not specified	Hand surgery	A4-sized document (8.27 × 1.69 inches) explaining risks (reading level not specified) in addition to standard verbal information versus standard verbal information only (control)	Risks	"A4 size questionnaire"	Delayed	High risk of bias	Neither
Alsaifari et al. (2016)	Canada	49	49.3 y (range 18–99)	Not specified	Total thyroidectomy	Pamphlet provided at the beginning of the informed consent interview (reading level not specified) and discussed point-by-point in addition to verbal consent with a senior staff surgeon following a standardized script versus verbal consent with a senior staff surgeon following a standardized alone (control)	Risks	12-item written multiple choice test	Delayed	High risk of bias	Intervention
Smith a et.al. (2012)	England	119	62.1 y (range 18–99)	Not specified		Surgeries for traumatic upper or lower limb fracture requiring surgical fixation	Risks	"Standardized, structured self-administered questionnaire"	Delayed	High risk of bias	Neither
Gangol et al. (2010)	Nepal	116	44.1 y	7.0% primary (1 to 3 classes), 32.3% secondary (4 to 10 classes), 11.4% higher (>10 classes)	Elective cholecystectomy	Information leaflet written in Nepali with information about indications, anesthesia, difference between laparoscopy versus open procedure, post-op pain control and diet, and complications (reading level not specified) given in addition to standard verbal counseling versus standard verbal counseling only (control)	Unclear/not specified	10 standard questions asked in interviews; each answer scored as 2 (understood well), 1 (understood), 0 (satisfactory/understanding), or 0 (poor understanding)	Not specified	High risk of bias	Intervention

\* Immediately: within 1 hour of informed consent consultation; early: >1 hour but <24 hours of informed consent consultation

Egekeze et al. (2016)	USA	67	54.2 y	All patients had a maximum completed level of academic achievement of a high school diploma	Knee corticosteroid injection	Group 1: control (10-minute informed consent discussion scripted at an eighth-grade reading level on the basis of information from the knee arthritis section of the patient education website OrthoInfo) Group 2: received the same verbal consent as the control group while watching a 10-minute animated knee anatomy video (played on silent, research staff member pointed images in the video during the discussion) Group 3: received the same verbal consent as the control group while holding an anatomic knee model; each participant touched specified aspects of the model that corresponded with the discussion	Unclear; not specified	14-item multiple choice questions in interview format with 20 minute time limit	Immediately	Some concerns for bias	Control: mean score 71% (10.0 out of 14) Group 2: mean score 74% (10.3 of 14) Group 3: mean score 84% (11.7 out of 14) $P = 0.019$	Group 3 > group 2 > control
Liu et al. (2018)	Taiwan	142	Not specified	15% less than high school, 37% high school, 48% college	Trauma-related debridement surgery	Educational video (~15 minutes duration) developed by a panel of experts describing the surgery, anesthesia, benefits, risks, alternatives, and post-op recovery using advanced 2D graphics, audio narrative, written subtitles and captions in addition to standard consent (verbal information plus written consent form with information about the surgery similar to that on the video plus educational session with health care provider) versus standard consent alone (control)	Risks, general knowledge about procedure	10-item multiple choice questionnaire	Immediately	Some concerns for bias	Mean knowledge score 72.57% intervention vs. 61.67% control, $P = 0.001$ Mean improvement in knowledge from baseline 18.71 (SD 6.44) intervention vs. 10.83 (SD 11.23) control, $P = 0.001$	Intervention
Huber et al. (2012)	Germany	220	63.4 y	8.9%, none or basic (missing school-leaving qualification or incomplete professional training), 52.7%, higher having passed senior technical college or university), 39.4% medium (all remaining patients)	Radical prostatectomy	Computer-based multimedia tool developed by an "interdisciplinary group" and tested with patients and "lay people" before completing the final version with an interface allowing the consenting physician to navigate between and highlight portions of graphics, illustrations, videos, and pictures in place of standard physician consent using a written consent form containing the same information (control)	Risks	"Remembered quantity" of risks	Early	Some concerns for bias	2.3 (SD 1.2) intervention vs. 2.4 (SD 1.4)	Neither
Baenninger et al. (2018)	Switzerland	113	35.3 y (range 19.7 - 57.1)	Not specified	Refractive excimer laser treatment for refractive ophthalmologic error	8-minute video of surgeon giving standard information and treating a patient plus further animations of the procedure in addition to conventional face-to-face consultation with a surgeon versus conventional face-to-face consultation with a surgeon alone (control)	Risks, general knowledge about procedure	25-item paper-based true/false questionnaire	Not specified	Some concerns for bias	22 out of 25 mean score for both intervention and control, $P = 0.975$	Neither
Vo et al. (2018)	USA	63	Not specified	Not specified	Cataract Surgery	American Academy of Ophthalmology enhanced surgery education video (4 minutes, 9 seconds long) prior to traditional face-to-face counseling with a surgeon versus traditional face-to-face counseling with a surgeon alone (control)	Risks, benefits, alternatives, general knowledge about procedure	Self-administered questionnaire with yes/no and 5 point scale items	Immediately	Some concerns for bias	79.4% (SD 2.42%) intervention vs. 79.3% (SD 3.59%) control, $P = 0.99$	Neither
Pallett et al. (2018)	USA	120	42.8 y	0.8% less than 24.6% high school, 74.6% higher education	Hysterectomy	10-minute video developed by the study investigators with audio script, illustrations and animations addressing 11 key aspects of the informed consent discussion plus standard physician counseling versus standard physician counseling covering the same 11 key aspects alone (control)	Risks, general knowledge about procedure	Questionnaire with true/false and multiple choice items with each subject given each version in a different order at 4 time points	Immediately and delayed	Some concerns for bias	Immediate: 15.1% improvement in score (SD 2.04%, intervention vs. 5.2%, SD 2.1%) control, $P = 0.009$ Delayed: day of surgery, 8.3% improvement in score (SD 2.3%, intervention vs. 1.2%, SD 2.01%, control, $P = 0.02$ ) Delayed: 6 weeks post consent: scores back to baseline for both groups	Intervention
Lattuca et al. (2018)	France	843	67.3 y	36% primary school, 48% secondary school, 16% university or higher	Coronary angiography	5-minute video with 3D animations developed for the study with content derived from the national information and consent form and approved by the scientific committee of the French Society of Cardiology displayed to each patient on an individual 10" tablet in addition to standard consent (oral (control))	Risks, general knowledge about procedure	16-item questionnaire	Immediately	Some concerns for bias	Overall score 11.8 intervention out of 16 (SD 3.1), $P < 0.001$	Intervention
Zhang et al. (2017)	China	80	Not specified	66% primary education, 23% secondary education or higher	Cataract surgery	6-minute educational video based on a video from the American Academy of Ophthalmology that included visual teaching aids, animation, music, and a script written in Mandarin and Cantonese by an expert in ophthalmological patient information needs <sup>§</sup> in addition to traditional verbal consent and consent documents alone (control)	Risks, benefits, alternatives, general knowledge about procedure	10-item yes/no questionnaire	Immediately	Some concerns for bias	Accuracy rate 80.2% intervention vs. 77.5% control, $P = 0.586$	Neither

Source	Study country	N	Mean patient age (and range if specified)	Patients' education	Procedure	Intervention	Elements of patient comprehension assessed	Comprehension assessment tool	Timing of patient comprehension assessment relative to informed consent consultation*	Risk of bias for patient comprehension outcome†	Results	Group favored‡
Armstrong et al. (2010)	USA	84	59.0 y	1.2% 1st through 8th, 17.9% 9th through 12th, 22.8% 1-3 years college, 57.1% 4 or more years college	Skin shave and punch biopsy	Dermatologists "obtained informed consent for skin biopsies using an educational video" with actual footage of shave and punch biopsy procedures displayed on a portable device (unclear whether in place of or in addition to standard consent versus traditional face-to-face consent with a dermatologist alone (control))	Risks, general knowledge about procedure	6-item multiple choice questionnaire	Immediately	Some concerns for bias	Knowledge score 1.55 out of 6 (SD 1.71) intervention vs. 1.12 out of 6 (SD 1.71) control, P = 0.259	Neither
Bowers et al. (2015)	Canada	93	60.9 y (range 19 - 89)	Not specified	Endovascular aneurysm repair, peripheral angioplasty, Hickman catheter and peripherally inserted central catheter insertion	2 minute computer-generated video presented on an electronic tablet by a medical student with simplistic anatomical visuals and information about the procedure after traditional verbal consent versus traditional verbal consent alone (control)	Risks, general knowledge about procedure	5-item written true/false test	Not specified	Some concerns for bias	"Intervention group had higher total comprehension scores" (numbers not reported)	Intervention
Clark et al. (2011)	USA	50	38.5 y	36% did not complete high school, 32% completed high school, 24% with some college or trade school, 8% with some graduate school	Elective cholecystectomy	PowerPoint presentation with illustrations of cholelithiasis and laparoscopy risks and complications explained "in the usual fashion" by general surgery residents using a checklist who had been trained for the study and monitored in a previous 10-patient pilot study) versus standard informed consent alone (control)	Risks, benefits, general knowledge about procedure	10-item true/false questionnaire	Not specified	Some concerns for bias	Correct response rate 66% intervention vs. 68% control, no P value provided	Neither
Mishra et al. (2010)	Scotland	84	66.6 y (range 62 - 71)	Not specified	Coronary artery bypass graft surgery	Group 1: control (standard informed consent consultation) Group 2: informed consent consultation audio-recorded then participants given a tape containing general information about CABG Group 3: informed consent consultation audio-recorded then participants given a tape recording of their own consultation interview Tapes were sent by mail with a letter encouraging patients to listen to them as many times as they wished	Unclear/ not specified	Validated 16-item questionnaire administered in person with each answer scored on a scale of 0 (inadequate) to 3 (very good)	Not specified	Some concerns for bias	Control: mean score 1.379 out of 48 (SD 5.554) Group 2: mean score 19.64 out of 48 (SD 3.451) Group 3: mean score 31.97 out of 48 (SD 5.922) P < 0.001	Group 3 > Group 2 > control
Han et al. (2016)	South Korea	40	66.9 y	37.5% did not complete high school, 32.3% completed high school, 30% university or more	High-performance system photo-selective vaporization of the prostate	Multimedia presentation containing the same content as conventional consent forms but utilizing pictures, illustrations, animations, and videos without voice-over explained by a physician in place of conventional consent (verbal explanation plus written document) versus conventional consent alone (control)	Risks, alternatives, general knowledge about procedure	15-item questionnaire	Immediately	Some concerns for bias	Mean score 10.6 out of 15 (SD 2.8) intervention vs. 9.9 out of 15 (SD 2.3) control, P = 0.332	Neither
Tipitsch-Maia et al. (2016)	Austria	123	71.9 y (range 56 - 90)	15% passed graduation examination	Cataract surgery	Computer-animated video in addition to standard consent (standardized face-to-face discussion following a checklist plus information brochure) versus standard consent alone (control)	Risks, alternatives, general knowledge about procedure	10-item multiple choice questionnaire	Immediately	Some concerns for bias	Mean number of correct answers 8.2 out of 10 (SD 0.5) intervention vs. 7.2 out of 10 (SD 0.7)	Intervention
Wysocki et al. (2012)	Poland	58	57.5 y	Not specified	Mastectomy	12-minute video with additional information adapted from the National Cancer Institute ( <a href="http://www.cancer.gov">www.cancer.gov</a> ) presented by breast cancer survivor in addition to routine informed consent (non-standardized conversation with the attending surgeon, practical information from nurses, basic informed consent form) versus routine informed consent alone (control)	Alternatives, general knowledge about procedure	"Self-administered questionnaire"	Early and delayed	Some concerns for bias	No overall score reported; greater percentage of intervention group correctly answered 1 question regarding treatment options within 24 hours and 7 days post-op (P = 0.010 and 0.036, respectively) with no difference between groups at 30 day post-op, and no difference between groups on two other questionnaire items P > 0.1	Neither
Choi et al. (2015)	South Korea	51	22.4 y (range 18 - 27)	19.6% up to secondary education, 80.4% postsecondary education	Impacted mandibular third molar removal	Narrated slideshow with simple illustrations created in PowerPoint by personnel at the Korean Academy of Dental Science™ including audio and visual cues plus standard informed consent document versus standard informed consent (verbal explanation plus Korean Dental Association Informed Consent Document)	Risks	Open-ended questionnaire form assessing recall of risks	Delayed	High risk of bias	No overall score reported; intervention group showed improvement over control in recall of only 2 out of 6 individual risks, P < 0.05, no significant difference in recall of all other risks, P > 0.1	Neither
Elliott et al. (2014)	Australia	41	36.1 y (range 19 - 51)	3% primary/20% secondary including year 10, 34% secondary years 11 and 12, 26% graduate degree, 8% postgraduate degree	Operative laparoscopy for investigation and treatment of pelvic pain	Routine, standardized surgical consent followed by a 15-minute educational multimedia module containing voice, script developed by the study authors, and 3D computer animations versus routine surgical consent alone (control)	Risks, benefits, general knowledge about procedure	14-item true/false/ unsure questionnaire	Immediately and delayed	High risk of bias	Immediate: mean score 11.3 out of 14 (SD 0.49) intervention vs. 7.9 out of 14 (SD 0.50) on immediate testing, P = 0.001 Delayed: no difference	Intervention
Karan et al. (2011)	India	60	63.1 y	Mean formal education in years: 5.0	Cataract surgery	24" × 36" poster displaying nine images in addition to scripted verbal informed consent read by a native Tamil speaker versus scripted verbal informed consent read by a native Tamil speaker alone (control)	Risks, benefits, general knowledge about procedure	Oral 11-item true/false/ don't know quiz	Immediately and early	High risk of bias	Immediate: mean score 8.17 out of 11 intervention vs. 8.13 out of 11 control, P = 0.956 Within 24 hours: mean score 8.71 out of 11 intervention vs. 7.39 out of 11 control, P = 0.0049, and mean improvement in score 3.6 intervention vs. 1.3 control, P = 0.002	Intervention

Source	Study country	N	Mean patient age (and range if specified)	Patients' education	Procedure	Intervention	Elements of patient comprehension assessed	Comprehension assessment tool	Timing of patient comprehension relative to informed consent consultation*	Risk of bias for patient comprehension outcome†	Results	Group favored‡
Winter et al. (2016)	Australia	88	54 y	27% did not complete high school; 73% secondary education or above	Cystoscopy and ureteric stent insertion	7:07-minute educational video with cartoon animation presented on an electronic tablet versus standard verbal consent with "urology registrar"	Unclear/ not specified	True/false and multiple choice questionnaire	Not specified	High risk of bias	23.26 out of 32 intervention vs. 20.13 out of 32 control; P < 0.001 17.8% increase in score when standard verbal consent group was crossed over to the intervention. P < 0.001 No significant difference in score when intervention group was crossed over to the control. P = 0.621	Intervention
Sharma et al. (2018)	USA	101	Not specified	Not specified	Functional endoscopic sinus surgery	One pre-operative and one immediate post-operative visit were video-recorded; intervention group was given access to their recordings via secured internet server to watch at their discretion, control group was not given access to their recordings	Risks, general knowledge about procedure	Paper-based questionnaire with multiple choice and yes/no items	Delayed	High risk of bias	Accurate recall of risks 66% intervention vs. 65% control Correct answers to questions regarding extent of surgery 4.46 out of 5 intervention vs. 4.27 out of 5 control "No statistically significant" (no P value given)	Neither
Wilhelm et al. (2009)	Germany	212	53.2 y	59.9% did not complete high school, 40.1% high school degree or higher	Laparoscopic cholecystectomy	26-minute DVD designed by the Institute of Media Informatics of the University of Munich and the Department of Surgery of the Technische Universität of Munich with text, 3D computer animations, video sequences, audio commentary, and an "education dialogue" between a surgeon and a patient as a patient in addition to standard informed consent with a surgeon versus standard informed consent with a surgeon alone (control)	Risks, general knowledge about procedure	25-item multiple choice questionnaire	Delayed	High risk of bias	Mean score 19.88 out of 25 intervention vs 17.58 out of 25 control	Intervention

\* Immediately: within 1 hour of informed consent consultation; early: >1 hour but <24 hours of informed consent consultation

† Assessed using the Cochrane Risk of Bias 2.0 tool, see Table 7 for details

Kostick et al. (2018)	USA	98	59.77 y (range 20 - 84)	60% high school degree/ GED, 40% some college	Left ventricular assist device implantation	Paper-based decision aid written at an 8th-grade reading level (took on average 59 minutes to review) with information about living with an LVAD, resources for patients and caregivers, narratives provided by patients and caregivers, risk and benefit information, and links to a website with supplemental informational videos	Risks, benefits, general knowledge about procedure	20-item multiple choice LVAD knowledge scale developed and validated by the research team	Immediately and delayed	Some concerns for bias	68% intervention vs. 59% control at one week follow up, P = 0.02 No significant difference at 1 month	Intervention

Source	Study country	N	Mean patient age (and range if specified)	Patients' education	Procedure	Intervention *	Elements of patient comprehension assessed	Comprehension assessment tool	Timing of patient comprehension assessment relative to informed consent consultation *	Risk of bias for patient comprehension outcome †	Results	Group favored‡	
Karan et al. (2014)	India	97	Not specified	Not specified	Cataract surgery	Patient Decision Aid Standards quality indicators versus "standard education" (control)	3-fold pamphlet designed by Unite for Sight, an ophthalmologist in Chennai, and a team of "visual communication specialists at a US-based university" plus patients were shown a 3D model of the eye in addition to scripted verbal informed consent read by a native Tamil speaker versus scripted verbal informed consent read by a native Tamil speaker only (control)	Risks, benefits, general knowledge about procedure	Validated 11-item true/false/ don't know quiz	Immediately and early	High risk of bias	Immediate: average difference in score from baseline 5.17 intervention vs. 1.52 control Within 24 hours: average difference in score from baseline 5.43 intervention vs. 1.06 control "P value on the order of $10^{-6}$ "	Intervention

\* Immediately: within 1 hour of informed consent consultation; early: >1 hour but <24 hours of informed consent consultation, delayed: 24 hours after informed consent consultation

† Assessed using the Cochrane Risk of Bias 2.0 tool, see Table 7 for details

‡ If a study reported an improvement in patient comprehension on a single item or multiple items of the comprehension assessment but if overall score did not improve, we considered neither or no group to be favored

**Table 6.**

Results of trials with multiple study groups receiving different intervention types to improve patient comprehension in informed consent

Source	Study country	N	Mean patient age (and range if specified)	Patients' education	Procedure	Intervention	Elements of patient comprehension assessed	Comprehension assessment tool	Timing of patient comprehension assessment relative to informed consent consultation*	Risk of bias for patient comprehension outcome†	Results	Group favored‡
Johnson et al. (2011)	USA	151	67 y	Mean education in years; 13	Total knee arthroplasty	Group 1: control (standardized informed consent using iMedConsent web-based tool plus customized written handout) Group 2: same as control plus a standard video from the American Academy of Orthopedic Surgeons (audiovisual intervention) Group 3: same as group 2 plus a "formal education session" (further details not provided) with a nurse coordinator/educator additionally reviewing risks, benefits, and expectations of total knee arthroplasty (multicomponent intervention)	Risks, benefits, alternatives, general knowledge about procedure	14-item multiple choice questionnaire	Immediately and delayed	High risk of bias	Control: immediate score 10.1 out of 14 (SD 2.4), day of surgery, score 10.2 out of 14 (SD 2.3), 6-week post op score 10.5 out of 14 (SD 1.7) Group 2: immediate score 10.8 out of 14 (SD 1.6), day of surgery, score 10.3 out of 14 (SD 2.7) Group 3: immediate score 11.1 out of 14 (SD 1.5), day of surgery, score 11.0 out of 14 (SD 1.2), 6-week post op score 10.4 out of 14 (SD 2.2)	None
