**ABSTRACT:** Inhibition of bacterial nitric oxide synthase (bNOS) has the potential to improve the efficacy of antimicrobials used to treat infections by Gram-positive pathogens *Staphylococcus aureus* and *Bacillus anthracis*. However, inhibitor specificity toward bNOS over the mammalian NOS (mNOS) isoforms remains a challenge because of the near identical NOS active sites. One key structural difference between the NOS isoforms is the amino acid composition of the pterin cofactor binding site that is adjacent to the NOS active site. Previously, we demonstrated that a NOS inhibitor targeting both the active and pterin sites was potent and functioned as an antimicrobial (Holden, et al., *Proc. Natl. Acad. Sci. U.S.A.* **2013**, *110*, 18127). Here we present additional crystal structures, binding analyses, and bacterial killing studies of inhibitors that target both the active and pterin sites of a bNOS and function as antimicrobials. Together, these data provide a framework for continued development of bNOS inhibitors, as each molecule represents an excellent chemical scaffold for the design of isoform selective bNOS inhibitors.
## INTRODUCTION

Structure-based drug design has played a key role in the development and characterization of isoform selective mammalian nitric oxide synthase (mNOS) inhibitors.[1,2] NOS, an enzyme responsible in mammals for the production of the essential signaling molecule NO, can also promote a variety of disease pathologies if production of NO is unregulated.[3] While structure-based inhibitor design efforts have largely focused on the three mNOS isoforms,[1,2] recent characterization of bNOS as an antibacterial target against Gram-positive pathogens *Staphylococcus aureus*[4,5] and *Bacillus anthracis*[6] has promoted interest in the development of potent bNOS inhibitors. Between several bacterial gene deletion experiments and biological assays it is clear that bNOS functions in Gram-positive pathogens to provide a protective barrier against a variety of antibiotics, oxidative stress, and host antimicrobial peptides.[4–7] Recently, we demonstrated that the effectiveness of a common antimicrobial is significantly improved when *B. subtilis*, a nonpathogenic model organism for *B. anthracis*, is also treated with a NOS inhibitor[8] originally designed to selectively inhibit mammalian neuronal NOS (nNOS).

One of the major issues in the design of bNOS inhibitors is its structural similarity to mNOS isoforms. Avoiding the inhibition of endothelial NOS (eNOS) and inducible NOS (iNOS) is important given the role these mammalian isoforms play in regulating blood pressure[9] and in the immune host defense system,[10] respectively. Direct comparison of the mammalian and bacterial NOS structures/sequences reveals several key differences that could be exploited for a bNOS inhibitor design effort. The first key difference is between the domain architecture of the NOS isoforms. Each mNOS is a multidomained protein composed of both a reductase and oxygenase domain whose activity is regulated by calmodulin. In sharp contrast, bNOS is only composed of an oxygenase domain and is not regulated by calmodulin. Because bNOS is not covalently linked to its redox partners like mNOS, bNOS must utilize redox partners for activity.[11,12] A second key difference is amino acid variances between the NOS active sites. For example, both bNOS and endothelial NOS (eNOS) have an Asn residue that directly interacts with the L-Arg substrate while this residue is Asp in nNOS and inducible NOS (iNOS). The active site Asp/Asn difference provided the initial structural underpinning for the design of nNOS selective inhibitors.[13] Despite this difference in electrostatics between bNOS and nNOS, inhibitors that target the Asn residue might be detrimental if they also inhibit the critical eNOS isoform. Additional active site differences in bNOS include His128 (mammalian equivalent is Ser) and Ile218 (mammalian equivalent is Val). The slightly bulkier Ile adjacent to the $O_2$ binding site has been shown to decrease the NO release rates in bNOS.[14] The last key difference between mNOS and bNOS is present at the pterin cofactor-binding site. Because bNOS lacks the N-terminal $Zn^{2+}$ binding motif present in mNOS, the pterin binding site is more exposed in bNOS,[14] resulting in weaker micromolar binding affinity in bNOS[15] vs the stronger nanomolar affinity in mNOS.[16] While the physiologically relevant bNOS cofactor that binds to the bNOS pterin site remains unknown,[17] inhibitors that target this site are an attractive avenue for structure-based drug design. These differences were first exploited by a NOS inhibitor that demonstrated antimicrobial properties against *B. subtilis*.[8]
Because NOS inhibitors that bind both the active and pterin binding sites could allow for further design of bNOS inhibitor specificity, we report here on several NOS inhibitors (1−7) we identified by solving crystal structures that target both the active and pterin binding sites of *B. subtilis* NOS (bsNOS). From initial analysis of NOS inhibitors (1−4), we were able to design and synthesize two additional inhibitors (5 and 6) that also targeted the active and pterin binding sites. Further characterization of inhibition was carried out using inhibitor binding assays, enzyme assays, molecular dynamics simulations, and bacterial assays to provide a structural framework for the continued design of isoform-selective bNOS inhibitors that function as antimicrobials.

## ■ RESULTS AND DISCUSSION

**Aminopyridine Inhibitor Binding.** Although *S. aureus* and *B. anthracis* are the primary targets, we use nonvirulent *B. subtilis* for routine screening. We also use *B. subtilis* NOS (bsNOS) for crystallography because bsNOS crystals diffract to much higher resolution than *S. aureus* NOS (saNOS) although the structures are identical. The root-mean-square standard deviation of Cα atoms between bsNOS and saNOS is 0.55 Å with 32−33 residues being identical within 10 Å of the heme iron. Therefore, structural insights gained from bsNOS are directly applicable to saNOS and *B. anthracis* NOS. Inhibitors 1−3 were initially designed to target nNOS and the structures of nNOS−1,2,3 have previously been reported.[18,19] The structures of bsNOS with inhibitors 1−6 revealed that each compound interacts with the active site Glu-243 and heme propionate D through a series of H-bonds between the aminopyridine functional groups (Figure 1A–D and Table 1). While 1 and 2 only differ in the amine substituent at the para-position of the aromatic ring linker, it is clear that linker composition between the aminopyridine groups dictates the orientation of the inhibitor and the rotameric position of Arg-247. For example, in 1, Arg-247 reorients to form a π−cation interaction with the aromatic ring of the linker. This alternative rotamer was also observed with 4. In sharp contrast, the linkers of 2 and 3 are parallel to the heme group, and Arg-247 is observed in its native position. In the case of 2, the parallel orientation (relative to the heme group) of the aromatic ring within the linker is likely a result of the H-bond formed between the linker's primary amine and heme propionate A.

Considering that a cyano substituent within the linker of 4 results in a π−cation interaction with Arg-247 and a H-bond between heme propionate D and the aminopyridine functional group, we anticipated that inhibitor binding to the pterin site could be further improved by addition of a secondary amino group to form an additional H-bond with heme propionate D and the cyano conjugated ring to maintain the π−cation interaction with Arg-247. These observations led to the synthesis of 5, whose linker unexpectedly adopted a parallel orientation to the heme group but maintained the π−cation interaction with Arg-247 (Figure 1E). To further improve inhibitor binding to the pterin site of bsNOS, we also synthesized 6; the design of 6 was based on the crystal structure of 2. The goal was to develop an inhibitor that formed a stable π−π stacking interaction with Trp-329 by replacing one of the aminopyridine groups of 2 with a pyrrolopyridine. The pyrrolopyridine should also be able to H-bond with heme propionate D. As observed with 2, compound 6 does indeed form a H-bond with the heme propionate and undergoes a π−π stacking interaction with Trp-329 as predicted from the modeling.

To further characterize inhibitor binding at the NOS active site, we measured the spectral binding constant, $K_S$, for each inhibitor to both bsNOS and iNOS. On the basis of the measured $K_S$ for each inhibitor, binding to both bsNOS and iNOS was in the low μM range (Table 2). In addition, we also measured $K_S$ for bsNOS in the presence and absence of H$_4$B. We anticipated the $K_S$ of inhibitors targeting the pterin site to increase in the presence of H$_4$B, as inhibitor binding would be weakened owing to competition with the pterin molecule. However, in the case of inhibitors that tightly bind to the pterin site, for example 1, only a 2-fold difference in binding was observed (Table 2), which we consider to be a negligible difference because the $K_S$ of ligands L-NNA and NOHA, two ligands that do not bind to the pterin site, resulted in a 3.4- and 1.2-fold difference in binding, respectively. Another interpretation is that the binding affinity of 1 to the pterin site is significantly stronger than the binding affinity of H$_4$B and that 1 is able to easily displace H$_4$B. If this is true, for tight binders the $K_S$ should remain unchanged in the presence or absence of H$_4$B. In contrast, for inhibitors that are transiently associated with the pterin site, as is observed with 5 and 6, it is not surprising that we also observe a negligible change in $K_S$ upon
**Figure 1.** Active site view of bsNOS−inhibitor bound crystal structures with the inhibitor colored yellow, heme colored salmon, and select active site residues colored white. Inhibitor−protein H-bond distances are represented as black lines. The $2F_O − F_C$ maps are shown for (A) **1** contoured at 1.8σ, (B) **2** contoured at 1.4σ, (C) **3** contoured at 1.2σ, (D) **4** contoured at 1.8σ, (E) **5** contoured at 2.0σ, and (F) **6** contoured at 1.3σ.

addition of $H_4B$ owing to the weak noncovalent interactions observed at the pterin site. Regardless, from the crystal structures (Figure 1), it is apparent that **1−6** may serve as reasonable templates for future structure-based drug design against bNOS, as all molecules do bind to the pterin-binding site.

**Thiophenecarboximidamide Inhibitor Binding.** Thiophenecarboximidamide inhibitors are expected to exhibit improved pharmacological properties over aminopyridine inhibitors but form similar complexes with nNOS,[20] so we investigated the binding of **7** to bsNOS. Similar to **1−6**, crystal structure analysis of **7** revealed that the inhibitor also bound at both the active and pterin sites (Figure 2A). Because **7** is an asymmetric inhibitor, with both ends of **7** being composed of a thiophenecarboximidamide, we wanted to investigate in more detail the noncovalent interactions that allow for the unique binding mode and orientation of **7** to bsNOS. From the crystal structures, we hypothesized that the inhibitor orientation observed in bsNOS-7 resulted from the 3.2 Å H-bond formed with His-128 and/or the hydrophobic contact shared between Ile-218 and one of the inhibitor aromatic rings. The observation of a 3.2 Å H-bond between **7** and His-128 (Figure 2A) was of particular interest because the corresponding residue in mNOS is a Ser. Similarly, it is feasible that the hydrophobic contact between Ile-218 and **7** would favor **7** to bind the aromatic ring lacking a polar substituent to form better nonpolar interactions with the larger Ile-218 side chain. However, site directed mutagenesis of bsNOS revealed that neither the H128S (Figure 2B) nor the I218V mutants (Figure 2C) resulted in an alternative bsNOS−7 binding mode. In fact, I218V-bsNOS resulted in a more stable H-bond, 2.7 vs 3.3 Å for WT, with His-128.

Together, these data suggest that the binding mode of **7** results from the ability of **7** to bind in the pterin pocket in order for **7** to optimally interact with both the pterin and active sites, and this is likely observed in bsNOS because pterin binding is weak. The importance of **7** binding to the pterin site is evidenced by the 6-fold decrease in affinity in the presence of $H_4B$ (Table 2).

To further probe the binding mode of **7** to bsNOS and investigate the H-bond contribution of His-128 to the binding mode, we ran MD simulations for 25 ns. After allowing the system to equilibrate for 4.5 ns, the ligand was allowed to freely move. In both WT and H128S MD simulations **7** retains its interactions with the active site Glu-243 (Figure 3A) and is loosely bound to heme propionate D (Figure 3B), suggesting that the H-bond formed between **7** and Glu-243 is strong and the H-bond between **7** and heme propionate D is weak. In fact, the bond distance between **7** and heme propionate D exceeded 3.5 Å for 96.4% of the bsNOS MD trajectory. Moreover, comparison of the MD trajectories for bsNOS and H128S-bsNOS suggests that the H-bond between **7** and His128 is also transient and does not contribute toward the binding mode of **7**. Distance measurements between the α-carbon of residue 128 and the hydroxyl group of **7** reveal His128 to function only by sterically restricting the movement of **7**, as the atom distances range from 2.6 to 7.6 Å for bsNOS−7 and 4.7 to 10.7 Å for H128S-bsNOS−7 (Figure 3C). This is not surprising as His is a much bulkier residue then Ser.

Interestingly, in both WT and H128S MD simulations, the thiophenecarboximidamide headgroup of **7** initially bound at the pterin site was observed to rotate in and out of the pterin pocket. This rotation of the thiophenecarboximidamide

between heme propionate D and the imine of **7** throughout the MD simulation revealed the distance between heme propionate D and the imine of **7** to be nonuniform within each chain of the bsNOS dimer (Figure 3B). Together, these data provide additional support that binding of **7** to the pterin site is relatively weak.

**Inhibition−Activity Analysis.** Both the aminopyridine and thiophenecarboximidamide based inhibitors bind and inhibit the three mNOS isoforms (Table 3). Considering **1−4** were originally designed to target nNOS, it is not surprising that **1−4** are good inhibitors of nNOS. Interestingly, a comparison of $K_i$'s for **2** and **6**, with **6** having a bulkier pyrrolopyridine group then the aminopyridine present in **2**, suggests the bulkier pyrrolopyridine group lowers the specificity toward the mNOS isoforms. Specifically, the potency of **6** toward nNOS decreased >4-fold as compared to the potency of **2** toward nNOS. Hence, the introduction of a bulkier group that also binds to the bNOS pterin site has the potential to lower inhibitor affinity to the mNOS isoforms.

With the use of the recently described bBiDomain and YumC system for bNOS activity/inhibition measurements, we also evaluated the potency of each inhibitor at varying concentrations using a single time point approach.[11] At all concentrations evaluated, **1** was the most potent, with 49.2 ± 1.2% nitrite detected at an inhibitor concentration of 300 μM. The increased potency of **1**, compared to **2−7**, is likely because **1** is able to form two separate 3.3 Å H-bonds with heme propionate D (Figure 1A), which accounts for an additional 1−3 kcal/mol in binding energy. Unlike **1**, compounds **2−6** are unable to form a strong H-bond with the heme propionate D (Figure 1). On the basis of this limited data set, it is clear that formation of a strong H-bond with heme propionate D improves inhibitor potency for molecules that target the pterin site. Moreover, of

the compounds evaluated here, it also is clear that inhibitor potency needs to be dramatically improved, as only one of these compounds lowered enzyme activity below 50% (Figure 4). The relatively weak potency observed might be the result of the inclusion of 50 $\mu$M $H_4B$ in the enzyme assay, as these inhibitors must compete with $H_4B$. Moreover, because the physiological pterin group[17] and its concentration within either *S. aureus* or *B. anthracis* is unknown, the actual in vivo potency may be substantially different from our in vitro results. Even so, the relative inhibitor potency of each inhibitor is a sufficient tool to guide inhibitor design. Therefore, improving the noncovalent protein−inhibitor interactions at the pterin-binding site will likely also improve inhibitor potency.

**Bacterial Growth Inhibition.** We previously showed that some NOS inhibitors developed for selective inhibition of nNOS worked synergistically with the antibiotic acriflavine (ACR)[8] to inhibit the growth of *B. subtilis*. In the previous work, there was a good correlation between the binding affinity of a NOS inhibitor to bsNOS and its ability to work synergistically with the antibiotic ACR in bacterial killing. We thus would expect inhibitor **1** to be especially effective at bacterial growth inhibition, and this indeed is the case (Figure 5). Of the inhibitors tested, **1** is the most effective at working

synergistically with ACR to block growth. With ACR alone, bacterial growth is 23% of control. In the presence of inhibitor **1** growth is 36% of control, but together with ACR the inhibition is close to 99%, clearly indicating a strong synergistic effect. While the correlation between being an effective bsNOS and a bacterial growth inhibitor are strong, **2** is an outlier. Inhibitor **2** does not bind as tightly to bsNOS nor is it as effective at blocking bsNOS activity, but it is, nevertheless, a good inhibitor of bacterial growth. Given that both **1** and **2** can inhibit bacterial growth on their own suggests that these compounds block bsNOS to render the bacteria more susceptible to ACR but may also influence additional non-bsNOS target(s).

## ■ CONCLUSION

Although the physiological pterin cofactor for bNOS remains unknown, NO production by bNOS requires the presence of a pterin group.[21] Because of this strict pterin group requirement for activity and the significant differences in the pterin binding sites between mNOS and bNOS, inhibitors that target the pterin site may provide the key to unlocking the design and development of potent bNOS inhibitors. By taking a structure-based approach toward the identification of NOS inhibitors, we were able to identify several chemical scaffolds that inhibit bsNOS by binding to both the active and pterin sites. Several of these structures resulted in unexpected rotameric positions of active site residue Arg-247. These alternate rotameric positions will be important to consider for future structure-based drug design. Moreover, while the crystal structures and $K_S$ analysis provide definitive support for each molecule binding at the active site, MD simulations suggest that the binding of **7** is transient and, therefore, weak. A particularly important observation is that aminopyridine inhibitors bind better than the pyrrolopyridine inhibitor even though both bind in the pterin pocket, form stacking interactions with Trp329, and H-bonds with the heme propionate. One might have expected the pyrrolopyridine to bind more tightly given the larger surface area that should form more extensive interactions with Trp329. However, a key difference between the aminopyridine group and the pyrrolopyridines is that the aminopyridine has a higher $pK_a$ than the pyrrolopyridine and is likely to be at least partially protonated and positively charged at neutral pH thus giving

**Figure 5.** NOS inhibitors influence the % survival of *B. subtilis*. (A) *B. subtilis* treated with NOS inhibitors. Significance calculated using the Student's *t* test between the measured CFU of *B. subtilis* treated with and without NOS inhibitors for each strain separately. (B) Bacterial survival of *B. subtilis* wt and Δ*nos* decreases in the presence of 800 $\mu$M ACR and 500 $\mu$M NOS inhibitors. Significance calculated for each strain separately using the Student's *t* test between the calculated % survival of ACR treated cells and % survival of ACR+NOS inhibitor treated cells. Error bars represent the mean ± the SEM of at least three replicates. Student's *t* test gives \*\*\**p* < 0.01, \*\**p* < 0.05, \**p* < 0.1.

stronger interactions with the heme propionate. This underscores the importance of strong electrostatic interactions with the heme propionate relative to $\pi$ stacking interactions. Further development of potent bNOS inhibitors that work synergistically with antibiotics will thus require further modification of inhibitor scaffolds that take these lessons into account.

## ■ EXPERIMENTAL PROCEDURES

**Site Directed Mutagenesis.** Active site mutations H128S and I218V were introduced using PfuTrubo (Agilent) on the previously reported bsNOS expression vector[8] containing sERP mutations E24A/E25A/E316A.[22]

**Expression and Purification.** Isolation of recombinant *B. subtilis* NOS, bBiDomain, and YumC from *Escherichia coli* were followed as previously reported.[11,14] The purification of mammalian NOS isoforms was also followed as previously reported.[23-25]

**Crystallization and Structure Determination.** bsNOS crystals were prepared, cryoprotected, and soaked with inhibitor as previously described for bsNOS−inhibitor complexes.[8] To obtain inhibitor bound crystal structures of compounds **5**, **6**, and **7**, H$_4$B was removed from the cryosoak. X-ray data were collected at both the Stanford Synchotron Radiation Light (SSRL) Source and the Advanced Light Source (ALS). Data sets were indexed and integrated with either imosflm[26] or XDS.[27] Aimless was used to scale the data sets.[28] Inhibitor restraints were constructed using PRODRG,[29] and data sets were refined using PHENIX.[30]

**Imidazole Displacement.** The transition from an imidazole bound low-spin to a ligand bound high-spin state was measured as previously described[8] using purified oxygenase domain of either bsNOS or iNOS. For trials that included H$_4$B, H$_4$B was added at 50 $\mu$M. The measured $K_{S,apparent}$ was used to calculate the $K_S$[31] using the bsNOS imidazole $K_D$ of 384 $\mu$M and iNOS imidazole $K_D$ of 158 $\mu$M.[32]

**Inhibition Assay using bBiDomain.** NADPH dependent *Bacillus subtilis* NOS activity/inhibition was evaluated using bBiDomain and the flavodoxin reductase YumC, as previously described,[11] with varying concentrations of inhibitor. Nitrite levels were measured as a function of NOS activity and calculated by the Griess reaction using a standard curve.

**Molecular Dynamics.** Starting coordinates for molecular dynamics simulations were generated from crystal structures of both bsNOS−7 and H128S-bsNOS−7. Because bsNOS is present as a dimer in solution,[33] a second subunit was generated from the crystal structure monomer using a C2 rotation axis. Hydrogens were added to the protein, **7**, and solvent using psfgen of VMD 1.9.1.[34] Bulk water was added to each system using the solvate command of VMD to generate a 25 Å cushion of solvent. As both structures were identical in overall size, the same unit cell box dimensions of (122 × 138 × 122) were used for each system. The final systems for bsNOS−7 and H128S-bsNOS−7 were composed of 194372 and 192503 atoms, respectively. Simulations were carried out on the Stampede supercomputer using NAMD 2.9.[35] The CHARMM force fields employed to model the protein and heme were identical to those used in previous simulations.[36,37] The CHARMM force field of **7** was generated using ParamChem (www.paramchem.org).[38] The smooth partial Ewald mesh method was used in the calculation of Coulombic forces, while a Langevin thermostat was employed for the constant temperature simulations.[39] Nosé−Hoover−Langevin piston was employed for pressure control.[40] All simulations were run at 300 K and 1 atm with a time step of 1 fs. All bonds involving hydrogen atoms were held fixed using the SHAKE algorithm.[41] Each structure was minimized for 1000 fs before the simulation was allowed to propagate. Positional restraints were placed on **7** during the first 4.5 ns of the simulation, allowing the protein to equilibrate before the inhibitor restraints were removed. Analyses of the simulations were carried out using locally developed analysis tools and VMD.[34]

**Effect of Antimicrobial Induced Stress and NOS Inhibitors on *B. subtilis*.** Isolation and characterization of *B. subtilis* Δ*nos* strain were previously described.[8] WT (American Type Culture Collection 23857) and Δ*nos B. subtilis* strains were grown separately to an OD$_{600}$ ≈ 1.0 and diluted to OD$_{600}$ = 0.6 in LB media. From the diluted cell stock, 80 $\mu$L was aliquoted into a sterile 1.5 mL Eppendorf tube and diluted to a final volume of 100 $\mu$L with M9 minimal media or a combination of either M9 minimal media, NOS inhibitor diluted in M9 minimal media, and/or acriflavine dissolved in M9 minimal media. Final concentrations of NOS inhibitor and acriflavine were 500 and 800 $\mu$M, respectively. Cells were treated for 30 min at 30 °C and then immediately serially diluted in M9 minimal media and plated on LB agar (supplemented with 0.5% glucose). Plates were incubated at 37 °C overnight. After overnight incubation, colony-forming units were counted and percent survival was calculated relative to the untreated cells.

**Chemical Synthesis.** Solvents were purified by passage through a solvent column composed of activated alumina and a supported copper redox catalyst. Reagents were purchased from Sigma-Aldrich and TCI America and were used without further purification. Normal phase flash column chromatography was performed using SuperFlash Si 50 prepacked silica cartridges and reverse phase flash column chromatography was performed using a SiliaSep C18 flash cartridge (25 g, 40−63 $\mu$m/230−400 mesh, pore size 60 Å) using 5−80% MeOH in water with an Agilent 971-FP flash purification system. $^{1}$H NMR and $^{13}$C NMR spectra were recorded in the indicated solvent on a Bruker Avance-III (500 and 126 MHz for $^{1}$H and $^{13}$C, respectively) spectrometer. MS was performed on a system consisting of an electrospray ionization (ESI) source in a Thermo Finnigan LCQ mass spectrometer. High resolution mass spectra were obtained using an Agilent 6210 LC-TOF spectrometer. The purities of the final compounds were evaluated on an Agilent 1260 analytical HPLC system using an Agilent Zorbax Eclipse XDB-C18 (4.6 mm × 50 mm, 5 $\mu$m) reverse phase column with UV absorbance and evaporative light scattering detection and were found to be ≥95%.

Compounds **1**, **2**, **3**, and **7** were obtained from previous studies.[18-20] To synthesize **4** (Scheme 1), Boc-protected 2-amino-4,6-dimethylpyridine (**8**) was treated with *n*-butyllithium and was mixed with 3,5-bis(bromomethyl)benzonitrile to give the corresponding intermediate (**10**). *N*-Methylation of **10** with 0.57 equiv of iodomethane and NaH followed by deprotection of the Boc protecting group gave target compound **4** in a moderate yield. The synthesis of **5** is shown in Scheme 2. Dibromophenethyl derivative **12** was prepared by coupling of 3,5-dibromobenzyl bromide with lithiated pyrrolyl-4,6-lutidine (**11**). This intermediate underwent microwave-assisted Rosenmund−von Braun reaction with CuCN to replace one of the bromides by CN (**13**). A Buchwald−Hartwig reaction of **13** with 2-pyridinylethylamine using Pd$_2$(dba)$_3$ and DavePhos gave the corresponding amine (**14**). The 2,5-dimethylpyrrole protecting group of **14** was removed with NH$_2$OH·HCl using a microwave[42] to generate **5**. Compound **6** was obtained using the synthetic pathway shown in Scheme 3. Sonogashira coupling between **13** and **15**[43,44] using Pd(PPh$_3$)$_2$Cl$_2$ yielded **16**. The produced alkyne of **16** underwent catalytic hydrogenation with Pd/C under hydrogen atmosphere. Microwave-assisted deprotection of the protecting groups on the aminopyridine ring with NH$_2$OH·HCl and Raney nickel mediated hydrogenation of the CN group yielded **6**.

**Spectral Data.** *Di-tert-butyl (((5-Cyano-1,3-phenylene)bis-(ethane-2,1-diyl))bis(4-methylpyridine-6,2-diyl))dicarbamate (10).* To a solution of *tert*-butyl (4,6-dimethylpyridin-2-yl)carbamate (**8**, 889 mg, 4.0 mmol) in THF (25 mL) was added *n*-BuLi (1.6 M solution in hexanes, 5.0 mL, 8.0 mmol). The reaction mixture was stirred for 30 min at 0 °C and was then cooled to −78 °C. To this solution, 3,5-bis(bromomethyl)benzonitrile (**9**, 578 mg, 2.0 mmol) in THF (2 mL) was added dropwise. After the mixture was stirred for an additional 10 min, it was quenched with H$_2$O (50 mL). The organic layer was partitioned by addition of ethyl acetate (50 mL), dried with MgSO$_4$, and concentrated in vacuo. The resulting brown oil was purified by flash chromatography (EtOAc/hexanes) to yield **10** (480 mg, 42%) as a pale-yellow oil. $^{1}$H NMR (500 MHz, CDCl$_3$) $\delta$ 7.64 (s, 2H), 7.50 (s, 2H), 7.29 (s, 2H), 7.19 (s, 1H), 6.57 (s, 2H), 2.96 (dd, $J$ = 9.3, 5.9 Hz, 4H), 2.90−2.80 (m, 4H), 2.30 (s, 6H), 1.52 (s, 18H). $^{13}$C NMR (126 MHz, CDCl$_3$) $\delta$ 158.25, 152.49, 151.52, 150.00,

*3-(2-(6-Amino-4-methylpyridin-2-yl)ethyl)-5-(2-(4-methyl-6-(methylamino)pyridin-2-yl)ethyl)benzonitrile (4).* To a solution of

Boc-protected aniline (400 mg, 0.70 mmol) in THF (2 mL), NaH (60% in oil, 17 mg, 0.4 mmol) was added at 0 °C. The reaction mixture was stirred for 15 min at the same temperature, and then methyl iodide (57 mg, 0.4 mmol) was added. The mixture was stirred

for an additional 12 h at room temperature, and then quenched with H$_2$O (10 mL). After addition of ethyl acetate (10 mL), the organic layer was partitioned, dried with MgSO$_4$, and concentrated in vacuo. The resulting brown oil was mixed with 1 M HCl solution in MeOH, stirred for 5 h, and then concentrated in vacuo to give crude **4**. The crude product was subjected to purification with a SiliaSep C18 flash cartridge (25g, 40−63 μm/230−400 mesh, pore size 60 Å) using 5−80% MeOH to give pure **4** (131 mg, 51%) as a colorless gel. $^1$H NMR (500 MHz, OD) δ 7.42−7.37 (m, 2H), 7.35 (s, 1H), 6.39 (s, 1H), 6.34 (s, 1H), 6.30 (s, 1H), 6.28 (s, 1H), 3.05−2.95 (m, 4H), 2.90 (s, 3H), 2.88−2.80 (m, 4H), 2.23 (s, 3H), 2.22 (s, 3H). $^{13}$C NMR (126 MHz, CD$_3$OD) δ 160.36, 159.46, 157.59, 156.34, 153.29, 152.08, 144.59, 144.14, 134.97, 131.04, 130.88, 119.92, 114.82, 114.20, 113.14, 108.87, 106.37, 39.12, 38.68, 36.25, 36.18, 29.16, 21.32, 21.26. HRMS (ESI): calcd for C$_{24}$H$_{28}$N$_5$ [M + H]$^+$, 386.2339; found, 386.2333.

*2-(3,5-Dibromophenethyl)-6-(2,5-dimethyl-1H-pyrrol-1-yl)-4-methylpyridine (12).* To a solution of **11** (1.2 g, 6.0 mmol) in THF (25 mL) was added *n*-BuLi (1.6 M solution in hexanes, 3.75 mL, 6.0 mmol). The reaction mixture was stirred for 30 min at 0 °C and transferred to a solution of 3,5-dibromobenzyl bromide (1.64 g, 5.0 mmol) in THF (25 mL) at −78 °C via cannula. The reaction mixture was allowed to stir for an additional 20 min and then quenched with H$_2$O (50 mL). After addition of ethyl acetate (50 mL), the organic layer was partitioned, dried with MgSO$_4$, and concentrated by rotary evaporation. The residue was purified by flash chromatography (EtOAc/hexanes) to yield **12** (86%) as a pale-yellow oil. $^1$H NMR (500 MHz, CDCl$_3$) δ 7.51 (s, 1H), 7.26 (ss, 2H), 6.91 (s, 2H), 5.92 (s, 2H), 3.06 (q, J = 2.8 Hz, 4H), 2.40 (d, J = 1.6 Hz, 3H), 2.15 (s, 6H). $^{13}$C NMR (126 MHz, CDCl$_3$) δ 159.76, 151.73, 149.72, 145.43, 131.65, 130.43, 128.48, 122.77, 122.74, 120.42, 106.76, 39.02, 34.89, 21.01, 13.27. MS ESI [M + H]$^+$ = 449. 3.

*3-Bromo-5-(2-(6-(2,5-dimethyl-1H-pyrrol-1-yl)-4-methylpyridin-2-yl)ethyl)benzonitrile (13).* A mixture of **12** (448 mg, 1.0 mmol), CuCN (108 mg, 1.20 mmol), and DMF (4 mL) was heated at 220 °C for 20 min in the microwave cavity. The reaction mixture was then treated with dichloromethane (20 mL), filtered, and concentrated in vacuo. The residue was purified by flash chromatography to give the **13** (225 mg, 57%) as a pale-yellow oil. $^1$H NMR (500 MHz, CDCl$_3$) δ 7.63 (s, 1H), 7.57 (s, 1H), 7.41 (s, 1H), 6.93 (ss, 2H), 5.92 (s, 2H), 3.19−3.03 (m, 4H), 2.41 (s, 3H), 2.13 (s, 6H). $^{13}$C NMR (126 MHz, CDCl$_3$) δ 159.27, 151.82, 149.88, 145.04, 136.39, 132.31, 130.76, 128.44, 122.77, 122.75, 120.59, 117.45, 113.92, 106.81, 38.69, 34.58, 21.01, 13.26. MS ESI [M + H]$^+$ = 394.5.

*3-(2-(6-(2,5-Dimethyl-1H-pyrrol-1-yl)-4-methylpyridin-2-yl)ethyl)-5-((2-(pyridin-2-yl)ethyl)amino)benzonitrile (14).* A mixture of 3-bromobenzonitrile **13** (200 mg, 0.5 mmol), 2-(2-pyridinyl)ethylamine (73 mg, 0.60 mmol), Pd$_2$(dba)$_3$ (23 mg, 0.025 mmol), DavePhos (20 mg, 0.050 mmol), and NaO*t*Bu (58 mg, 0.60 mmol) in THF (1.5 mL) and 1,4-dioxane (1.5 mL) was stirred at 80 °C for 12 h. The reaction mixture was then treated with diethyl ether (20 mL), filtered, and concentrated in vacuo. The residue was purified by flash chromatography (EtOAc/hexanes) to give **14** (157 mg, 72%) as a pale-yellow oil. $^1$H NMR (500 MHz, CDCl$_3$) δ 8.62−8.55 (m, 1H), 7.65 (td, J = 7.6, 1.9 Hz, 1H), 7.22−7.16 (m, 2H), 6.93 (s, 1H), 6.88 (s, 1H), 6.77 (s, 1H), 6.67 (s, 1H), 6.64 (s, 1H), 5.91 (s, 2H), 4.65 (t, J = 5.6 Hz, 1H), 3.50 (q, J = 5.8 Hz, 2H), 3.15−3.03 (m, 4H), 3.02−2.93 (m, 2H), 2.39 (s, 3H), 2.20 (s, 6H). $^{13}$C NMR (126 MHz, CDCl$_3$) δ 160.25, 159.34, 151.66, 149.62, 149.37, 148.54, 143.70, 136.75, 128.45, 123.39, 122.65, 121.73, 120.69, 120.25, 119.66, 117.48, 112.99, 112.70, 106.72, 43.09, 39.17, 36.83, 35.43, 21.01, 13.25. MS ESI [M + H]$^+$ = 436.5.

*3-(2-(6-Amino-4-methylpyridin-2-yl)ethyl)-5-((2-(pyridin-2-yl)-ethyl)amino)benzonitrile (5).* To a 5 mL microwave vial was added protected aminopyridine **14** (131 mg, 0.3 mmol), hydroxylamine HCl (105 mg, 1.5 mmol), EtOH (1.5 mL), and H$_2$O (0.5 mL). After being sealed, the vial was shaken vigorously and then heated in the microwave irradiator for 30 min at 120 °C. The reaction mixture was allowed to cool to room temperature and then concentrated in vacuo and purified by flash column chromatography using a SiliaSep C18 flash cartridge (25 g, 40−63 μm/230−400 mesh, pore size 60 Å) with

5−80% MeOH in water to yield **5** (76%) as a pale-yellow gel. $^1$H NMR (500 MHz, CDCl$_3$) δ 8.63−8.53 (m, 1H), 7.65 (td, J = 7.7, 1.8 Hz, 1H), 7.20 (dd, J = 7.6, 5.6 Hz, 2H), 6.81 (s, 1H), 6.67 (d, J = 1.4 Hz, 2H), 6.32 (s, 1H), 6.20 (s, 1H), 4.60 (t, J = 5.6 Hz, 1H), 3.51 (q, J = 6.2 Hz, 2H), 3.09 (t, J = 6.5 Hz, 2H), 2.91 (dd, J = 9.5, 5.7 Hz, 2H), 2.82 (dd, J = 9.5, 5.7 Hz, 2H), 2.20 (s, 3H). $^{13}$C NMR (126 MHz, CDCl$_3$) δ 159.38, 158.81, 158.22, 149.39, 149.27, 148.45, 144.12, 136.72, 123.39, 121.71, 120.89, 119.76, 117.54, 114.52, 112.88, 112.61, 106.68, 43.12, 39.34, 36.88, 35.68, 20.97. HRMS (ESI): calcd for C$_{22}$H$_{24}$N$_5$ [M + H]$^+$, 358.2026; found, 358.2024.

*6-Ethynyl-1H-pyrrolo[2,3-b]pyridine (15).* Compound **15** was prepared as previously described,[41,42] and the spectral data were in accordance with those previously reported.

*3-((1H-Pyrrolo[2,3-b]pyridin-6-yl)ethynyl)-5-(2-(6-(2,5-dimethyl-1H-pyrrol-1-yl)-4-methylpyridin-2-yl)ethyl)benzonitrile (16).* A mixture of **13** (394 mg, 1.0 mmol), **15** (156 mg, 1.1 mmol), Pd(PPh$_3$)$_2$Cl$_2$ (35 mg, 0.05 mmol), CuI (10 mg, 0.05 mmol), PPh$_3$ (52 mg, 0.20 mmol), diethylamine (2 mL), and DMF (2 mL) was heated at 120 °C for 20 min in the microwave cavity. Then the reaction mixture was treated with diethyl ether (20 mL), filtered, and concentrated in vacuo. The residue was purified by flash chromatography (EtOAc/hexanes) to give **16** (405 mg, 89%) as a pale-yellow oil. $^1$H NMR (500 MHz, CDCl$_3$) δ 11.54 (s, 1H), 8.00 (d, J = 8.0 Hz, 1H), 7.71 (t, J = 1.6 Hz, 1H), 7.68 (t, J = 1.7 Hz, 1H), 7.45 (dt, J = 3.4, 2.1 Hz, 2H), 7.39 (d, J = 8.0 Hz, 1H), 6.95 (d, J = 1.3 Hz, 1H), 6.92 (d, J = 1.3 Hz, 1H), 6.57 (dd, J = 3.5, 1.9 Hz, 1H), 5.93 (s, 2H), 3.17 (h, J = 2.6 Hz, 4H), 2.41 (s, 3H), 2.16 (s, 6H). $^{13}$C NMR (126 MHz, CDCl$_3$) δ 159.58, 151.80, 149.89, 148.47, 143.47, 136.14, 134.18, 132.66, 131.91, 129.07, 128.48, 127.35, 124.33, 122.78, 120.79, 120.56, 119.87, 118.16, 112.89, 106.82, 101.20, 91.73, 85.40, 38.75, 34.78, 21.04, 13.29. MS (ESI) *e/z* = 456.3 [M + H]$^+$.

*3-(2-(1H-Pyrrolo[2,3-b]pyridin-6-yl)ethyl)-5-(2-(6-amino-4-methylpyridin-2-yl)ethyl)benzonitrile (17).* After stirring **16** (400 mg, 0.88 mmol) and Pd/C (10%, 200 mg) in EtOH (10 mL) for 30 min at ambient temperature under a hydrogen atmosphere, the reaction mixture was filtered through Celite and concentrated in vacuo. The residue was mixed with hydroxylamine HCl (308 mg, 4.4 mmol), EtOH (1.5 mL), and H$_2$O (0.5 mL) in a microwave vial. The vial was capped, shaken vigorously, and then heated in the microwave irradiator for 30 min at 120 °C. After cooling the vial to room temperature, the reaction mixture was concentrated in vacuo and purified using a SiliaSep C18 flash cartridge (25g, 40−63 μm/230−400 mesh, pore size 60 Å) with 5−80% MeOH to give pure **17** (180 mg, 57%) as a pale-brown gel. $^1$H NMR (500 MHz, CD$_3$OD) δ 7.89 (d, J = 8.0 Hz, 1H), 7.39 (s, 1H), 7.35−7.31 (m, 2H), 7.27 (s, 1H), 6.91 (d, J = 8.0 Hz, 1H), 6.46 (d, J = 3.5 Hz, 1H), 6.28 (s, 1H), 6.21 (s, 1H), 3.10 (td, J = 5.1, 4.0, 2.6 Hz, 4H), 2.92 (dd, J = 9.1, 6.7 Hz, 2H), 2.72 (dd, J = 9.1, 6.7 Hz, 2H), 2.17 (s, 3H). $^{13}$C NMR (126 MHz, CD$_3$OD) δ 160.67, 158.71, 154.78, 151.29, 149.18, 144.64, 144.53, 135.00, 130.88, 130.83, 130.58, 126.30, 120.33, 120.00, 116.62, 114.81, 113.01, 108.12, 101.30, 40.35, 39.87, 37.17, 36.50, 21.01. HRMS (ESI): calcd for C$_{24}$H$_{24}$N$_5$ [M + H]$^+$, 382.2026; found, 358.2027.

*6-(3-(2-(1H-Pyrrolo[2,3-b]pyridin-6-yl)ethyl)-5-(aminomethyl)-phenethyl)-4-methylpyridin-2-amine (6).* A solution of **17** (100 mg, 0.28 mmol) in MeOH (10 mL) was stirred with Raney-Ni (50% in water, 0.2 mL) for 1 h at ambient temperature under a hydrogen atmosphere. The reaction mixture was filtered through Celite, concentrated in vacuo, and purified using prep-HPLC to yield **6** (63 mg, 62%). $^1$H NMR (500 MHz, CD$_3$OD) δ 8.31 (s, 2H), 7.74 (d, J = 7.9 Hz, 1H), 7.18 (d, J = 3.5 Hz, 1H), 7.05 (s, 1H), 7.02 (s, 1H), 6.93 (s, 1H), 6.80 (d, J = 7.9 Hz, 1H), 6.77−6.67 (m, 1H), 6.35 (s, 1H), 6.31 (d, J = 3.5 Hz, 1H), 6.27 (s, 1H), 3.92 (s, 2H), 2.98 (dd, J = 8.7, 5.6 Hz, 2H), 2.92 (dd, J = 8.6, 5.6 Hz, 2H), 2.81 (t, J = 7.6 Hz, 2H), 2.72 (t, J = 7.4 Hz, 2H), 2.13 (s, 3H). $^{13}$C NMR (126 MHz, CD$_3$OD) δ 157.84, 156.30, 155.35, 149.22, 144.46, 142.96, 134.90, 130.80, 130.53, 128.24, 127.83, 126.42, 120.45, 116.61, 115.67, 114.68, 110.01, 101.45, 44.42, 40.77, 37.78, 37.05, 36.31, 21.73. HRMS (ESI): calcd for C$_{24}$H$_{28}$N$_5$ [M + H]$^+$, 386.2339; found, 386.2338.

## ASSOCIATED CONTENT

### Accession Codes

Atomic coordinates and structure factors for compounds **1**−**7** complexed to wild type bsNOS and **7** complexed the H128S and I218V have been deposited in the Protein Data Bank with the ID codes 4D3J, 4D3I, 4D3K, 4D3M, 4D3N, 4D3O, 4D3T, 4D3U, and 4D3V, respectively.
