## Frontiers in Squid Reproduction: Prospecting for New Antibiotics

David Epel

Stanford University—Hopkins Marine Station

### Background

Many strains of disease-causing bacteria have become resistant to antibiotics, leading those in the medical profession to search for new sources of drugs.

Although most antibiotics have been derived from terrestrial life, it is the marine world that may provide the pharmaceutical industry with the next generation of medicines. The biochemistries of seemingly simple marine organisms such as blue-green algae, sponges and squid are inspiring new ideas for drug development.

### The Project

Marine biology professor Dr. David Epel of Stanford University was funded to study the antimicrobial properties of coatings on squid egg sheaths. Recent studies have shown that female squid inoculate their eggs with a paste that protects the eggs from fungi, bacteria and parasites during their one-month incubation on the seafloor.

It is hoped that these protective coatings work through biochemical pathways that have not been seen in terrestrial animals. Such compounds offer the best defense

against a growing number of antibiotic-resistant diseases.

In previous Sea Grant research, Dr. Epel's laboratory isolated two novel types of bacteria—a *Shewanella* sp. and *Roseobacter* sp.—from the eggs and accessory nidamental glands of the California market squid (*Loligo opalescens*). The accessory nidamental glands are reproductive organs located beside the egg-producing nidamental glands. They also harbor a dense bacterial community that is secreted onto the eggs. These bacteria are collected from seawater by female squid.

In this project, Dr. Epel and post-doctoral researcher Dr. Todd Ciche continued their examination of these protective bacteria, using a molecular technique that allows them to identify all the different types of bacteria present on squid eggs.

Using this new technique, Drs. Epel and Ciche have discovered about eight previously unknown kinds of bacteria in the egg sheath of the market squid. The researchers have also succeeded in growing most of these new bacteria in culture. In earlier experiments, they were unable to do this.

### The Findings

Only one of the 10 bacterial species was shown to produce antibacterial compounds. Based on this, the scientists hypothesize that the group of bacteria work in concert, communicating through chemical signals, to produce antibiotic and anti-fungal compounds. Thus, although most bacteria may not directly produce protective compounds, they may play a key role in signaling other bacteria to produce them.

In subsequent experiments, Drs. Epel and Ciche have characterized the bacteria in the egg coatings of two other species of squid—one native to Hawaii and the other native to the Mediterranean Sea. Although the squid species have geographically distant ranges, their egg sheaths contain several of the same

bacteria found in the sheaths of the California market squid. The finding suggests that these common bacteria are involved in a common biological process, and that the bacteria and their protective function

have remained unchanged during the many millions of years it took for the different squid species to evolve.

Drs. Epel and Ciche's future work will focus on isolating and describing the antibiotics present in the egg coatings. They also plan to study the communication mechanism among the different species of bacteria.

*California Sea Grant is a statewide, multiuniversity program of marine research, education, and outreach activities, administered by the University of California. Sea Grant-sponsored research contributes to the growing body of knowledge about our coastal and ocean resources and, consequently, to the solution of many marine-related problems facing our society. Through its Marine Extension Program, Sea Grant transfers information and technology developed in research efforts to a wide community of interested parties and actual users of marine information and technology, not only in California but throughout the nation. Sea Grant also supports a broad range of educational programs so that our coastal and ocean resources can be understood and used judiciously by this and future generations.*

*The national network of Sea Grant programs is a unique partnership of public and private sectors, combining research, education, and technology transfer for public service and dedicated to meeting the changing environmental and economic needs in our coastal, ocean, and Great Lakes regions.*

*This work is sponsored in part by a grant from the National Sea Grant College Program, National Oceanic and Atmospheric Administration, U.S. Department of Commerce, under grant number NA06RG0142, Project number A/P-1.
