## Unit 46: Address Matching

Written by Susan Jampoler, Geoknowledge

### Context:

Address matching allows the user to convert postal addresses and/or zip codes to geographic coordinates, create a new data layer containing these points, and display the information on a map. Three components are necessary to complete the address matching process: a geographic base file (GBF), a table containing address information, and a computer software package that performs the conversion. Address geocoding functionality is available in most geographic information system (GIS) software packages. The resultant new point data layer can subsequently be used to analyze spatial patterns.

The following examples are typical problems where address geocoding can be applied. Often, just visualizing the information on a map is enough to answer the questions. However, the geocoding process is frequently a preliminary step used in preparing the information for further spatial analysis.

### Example Applications

#### 1. Medical

You work in the MIS division of a health maintenance organization (HMO) which has recently received several complaints from participants. Waiting time to get an doctor's appointment is excessive and patients must travel too far when they need to see a specialist. Several participating companies are considering switching to another health care service. In order to retain these organizations, your senior management has asked you to evaluate where to increase physician coverage and how to improve service.

You maintain several databases, including information on participating companies, individuals, physicians, and local hospital and diagnostic facilities. It is hard to visualize where patients live, or where doctors and facilities are located by sorting and studying these databases. Fortunately, all the databases include a field containing address information.

The first task is to convert those addresses to points on a map using address geocoding. You will need to obtain a geographic base file, probably from a commercial vendor. Using the GBF and your databases, you now create new point data layers which show the distribution of patients, physicians, hospitals and diagnostic centers. You will then need to know where other doctors not currently in your HMO are located. You can purchase this information from several vendors using the standard industrial classification (SIC) for the type of doctors you need, and add the layer to your analysis. Finally you will use other GIS capabilities to determine where to recruit additional physicians.

## **2. Local Government**

Each day, citizens and builders come into your department to obtain building permits. Your supervisor wants a monthly report describing the number, type and distribution of permits throughout the county. Until now, you have provided some charts that show the volume of permits according to type (room additions, driveway repair, swimming pool, deck, etc.) and by requester. You have located the permits using a push pin on a paper map. Your county has experienced a rapid increase in the number of permits requested and it is taking you a full day each month to create your map. There must be an easier way! Address geocoding will allow you to locate each permit by using the work site address in your permits database and the street centerline file (the GBF) that your county's mapping division has just completed. You can now make several maps. For example, you can provide a map showing all permits for the month, reclassify the information by permit type or requester, and show change from one month to the next using historical information.

## **3. Distribution**

You work for a specialty attire company. Your product is very popular in large metropolitan areas throughout the United States, particularly in the west and south. You currently have two distribution centers, one in the east and one in the west. The stores that carry your attire in the west are complaining that your product is not arriving on time. Your western distribution center is overwhelmed and is not capable of completing all the delivery orders. Clearly, you need an additional distribution center. Your task is to choose the correct location. Location analysis is a complicated process and involves many GIS operations. Geographic information you must consider includes, but is not limited to: local zoning, supplier location, means of delivery (both how you receive and how you send out your goods), and customer location. To map your customer locations you will use address geocoding using your customer database and an available geographic base file. This base file can be a zip code, zip+4, TIGER or TIGER derivative file that you purchase. The points representing your customers will then be considered in the geographic analysis when locating your new distribution center.

## **4. Marketing**

You work for a national computer chain in the direct mail department. You send out a mass mailing once a month advertising sales. Rather than sending out just one generic mailing, you want to develop advertisements that will appeal to the postal patron. For several months your company has been asking customers for their zip code when they make a purchase as part of a "market survey to determine where to place new stores". The company now has a large

database that includes everything that was purchased. You can map this information using address geocoding and then reclassify and sort the data to show spatial patterns. For this problem, you need your database and a zip code geographic base file. Once you see the map, it will help you know what products are selling in a specific area. You can then advertise complementary products and increase your sales.

---

## Learning Outcomes

**The following list describes the expected skills that students should master for each level of training i.e., Awareness/Competency/Mastery.**

### Awareness:

The learning goals are to identify sources and to develop a working knowledge of the three components necessary to complete the geocoding process: the geographic base file, the address file and the software. (Suggested time: one 50 minute unit)

### Competency:

The learning goals are to define and evaluate appropriate base files, understand the importance of standardized address files, bring the necessary files into a software package, perform the geocoding process, and visualize the results. (Suggested time: one 50 minute unit and one 50 minute lab)

### Mastery:

The learning goals are to effectively evaluate the accuracy of both base files and address files, standardize address files, evaluate non-matches, understand the rematch process, and perform a basic reclassification analysis using attribute information provided in the address file. (Suggested time: one 50 minute unit)

---

## Preparatory Units:

### Recommended Units:

Unit 1 Data acquisition

Unit 2 Demographic data

Unit 19 Planning a tabular database

Unit 21 Using spreadsheets

Unit 30 Validating databases

Unit 31 Managing database files

Highly recommended background for instructor

Unit 016 NCGIA Core Curriculum in GIScience: Discrete Georeferencing

**Complementary Units:**

Unit 7 Metadata

Unit 47 Visualization

---

**Awareness**

**Learning Objectives:**

- Identify sources of geographic base (reference) files.
- Identify sources of address files.
- Determine address geocoding applications.
- Evaluate desktop mapping software.
- Understand the components of address geocoding.

**Topics:**

1. Identify sources of geographic base (reference) files

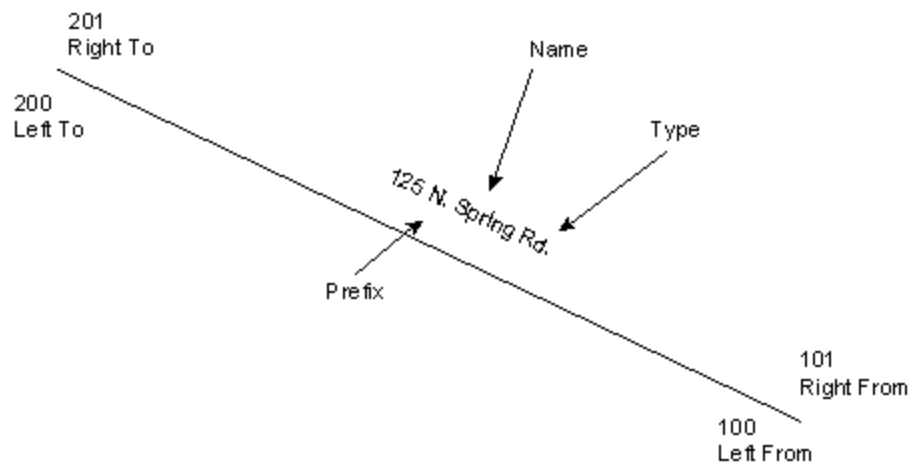

- Government sources
  - TIGER: U.S. Bureau of the Census
    - Available on CD, from libraries, on-line (Census Tiger Files)
    - Must be converted to appropriate software format
    - Line files that are organized by county and contain:
      - Roads, railroads, rivers
      - Census statistical boundaries
      - Political boundaries
      - Metropolitan address ranges and zip codes for streets
- Local government: County mapping organizations
  - Normally only available in the format supported by the county
  - Requires conversion to appropriate software format

- Data vendors
  - Can be purchased from a variety of vendors
  - Enhanced TIGER files
  - May be more accurate and up-to-date (location and attribute)
  - Converted to specific software format

[\(full image\)](#)

Example of enhanced tiger format (Note: the address is separated into several fields)

Graphic 1: Example of a GBF road: inset

## 2. Identify sources of Address files

- Any organizational data base that contains a field with address information  
i.e., customer records, permit sites, crime locations, school children, store locations, disease outbreaks

[\(full image\)](#)

Example of an address file (Note: The address is in one file)

- Can be purchased address files, usually collected through yellow pages entries

i.e., fast food restaurants, hospitals, child care centers, competitor's locations

- Available on-line, on CDROM (Unit 016 NCGIA Core Curriculum in GeoScience, section 5.1.1)

### 3. Determine address geocoding applications

- Identifying location  
i.e., customers, competitors, permits, crimes, fires, available real estate
- Siting facilities  
i.e., existing distribution centers, health care providers, service facilities
- Determining patterns:  
i.e., fires near schools, potential customers not served by a store
- Delivery:  
i.e., mail, mass mailing, goods, services
- Market analysis  
i.e., location of competitors
- Anytime the location cannot be directly georeferenced

### 4. Evaluating desktop software

- Most desktop packages have address matching capabilities
- Some packages come with geographic base files
- Software must incorporate the capability to:
  - Be tolerant of errors in address files
  - Allow for consideration and review of "almost" matches
  - Provide for changing the
    - Matching rules
    - Data tables
    - Cut-off thresholds

- Operate in both sequential batch and single event modes
5. Understand the components of address geocoding
- Reference Files (Geographic Base Files (GBF))
    - i.e., street network, zip codes
  - Table of addresses and other attribute information
    - i.e., crime data, customers, store locations
  - Software
- 

## Competency

### Learning Objectives:

- Evaluate appropriate reference files.
- Evaluate address files for completeness and standardization.
- Perform address matching operations.
- Perform visual analysis of resulting point data layers.
- Practical Exercise: geocoding.

### Topics:

#### 1. Evaluate appropriate reference files

- Detail and accuracy of the address file
  - Contains full address or just zip code information?
  - Contains direction information (i.e., N. Main St. or Main St.)?
- Range of detail in reference files
  - Single field

i.e., zip code, address all in one field, zip+4

- Single house with range

i.e., house number, range along a street, no information on what is on the left or right side of the street

- U.S. streets with zones

i.e., house, range along a street, information on what is on the left or right side of the street

[\(full image\)](#)

Example of zip code base file

[\(full image\)](#)

Example of US Streets base file

- Determine geographic extent of the application

- Local, regional or national

- More detailed reference files cost more to acquire

Ask: Does application support increased resolution of the reference file?

(i.e. rural routes should not use street style addresses)

- Successful implementation requires

- Careful data preparation

- Selecting the appropriate geocoding preferences in the geographic base file used to match to the address file

## 2. Evaluate address file for completeness and standardization

- Addresses provide information about the location of an event or an incident

- Usually collected without regard to standard format: no standard method for

## identifying features

i.e., Ave., Avenue, Av all stand for the same feature type  
 Direction sometimes a suffix, sometimes a prefix

- Often contain errors and omissions
  - i.e., Spelling errors, duplicate records, data base not up to date
  - i.e., Phonetic errors, transpositions, random letter insertion, character deletion or replacement
- Files can be commercially standardized using U.S. Postal Service format
- The more complete and standardized the address file, the more successful the address matching process

## 3. Perform address matching operations

- Prepare the data
  - Identify the base and address files
  - Define the address style

[\(full image\)](#)

Example of US Streets address style (Note: Some fields are required, others are optional but may provide a higher match success rate if used to index the base file)

[\(full image\)](#)

Example of address file

- Define matching strategies for reference and address files

What fields need to be indexed?

What fields will be matched?

What is a match?

### What about errors?

- Standardize the base and address files
- Prepare the base file: Separate data into individual fields and standardize abbreviations (this is usually done by the data provider)
- Index

[\(full image\)](#)

Example of defining the index process

- Prepare the Address Table by separating the data into individual fields and sorting (this is done by the software)
- Match the address file to the GBF
  - Set up the match process by identifying how the address file will link to the base reference file by defining the comparison methods (this is done by the software based on the parameters you have set)
    - Compares the address file to the base reference file field by field
      - i.e., prefix direction, prefix type, street type, suffix direction
    - Compares the address character-by-character
      - i.e., Main compared to Maine
    - Specify probabilities to compute matching score

[\(full image\)](#)

Example of setting the matching parameters (Note: In this ArcView example you 1) identify the GBF; 2) identify the address file and address field; and, 3) set the comparison preferences.)

- Perform the match
  - Software scores how close a match is found
  - Interpolates along the street network to determine the address location

[\(full image\)](#)

Example of how the software compare the address file to the base reference file (Note: The software determines possible matches to the address file in the GBF and picks the best match based on the parameters set.)

- Create the new geographic data layer containing one point for each address found
4. Perform visual analysis of resulting point data layers
- Display the resulting geographic point data layer
  - Relate new information to other pieces of information
5. Practical Exercise: Geocoding

Address geocoding capabilities are available in most desktop packages. This exercise uses ArcView Version 3.0a. The data sets and an ArcView project for the exercise can be downloaded [\[link removed\]](#). They are in ArcView shapefile.

You work for the Office of Economic Development in San Antonio, Texas, and are doing a market survey to determine how many aircraft manufacturing facilities are in San Antonio, and where they are located. You want to use address geocoding to create a map of the facilities. The three steps you will take are to:

- 1) prepare the data;
- 2) match the addresses; and,
- 3) display the results.

**Prepare the data:** You obtain the addresses of manufacturing plants through the electronic yellow pages [\[outdated link removed\]](#). You create a database containing this information and obtain a geographic base reference file from a local data provider. Your third piece of information is the location of airfields within the San Antonio area. You open your GIS desktop software package and add your database (the aircraft manufacturers) plus the two geographic data layers (airports and streets).

[\(Example of how this view may look.\)](#)

You are now ready to index the geographic base file so the software can compare the information in the aircraft manufacturers [address table](#) to your geographic [base file](#) (streets). Let's take the case of Zee Systems, Inc., which

has an office at 406 West Rhapsody Drive. The software will take the address from the database. It will then look for all the Rhapsody Drive street segments in the geographic base file ([see example](#)). Using the match rules you set up, it will exclude any streets that are on East Rhapsody, identify the segment going from 306 to 598 West Rhapsody, and interpolate that the office is about 2/3 of the way down the street the right side. ([see example](#)) Once the match is identified, a new record is added to your point data layer of aircraft manufacturing facilities and the results are displayed on your map.

In order for the software to make this comparison between a geographic data layer and address table, you must complete several steps. The first step is to determine the type of base file you have. In this example, you are using a US Streets [formatted file](#). When using US street format, your database must contain fields holding the left address from, left address to, right address from, right address to, and street name. Optional fields can contain the street type, prefix or suffix and direction. ([see example](#)). Notice that the necessary fields are available. This database is complicated by having two direction fields (prefix and suffix). You can specify both when setting up the index parameters. In ArcView, you need to set the Theme Preferences to recognize that the data layer contains US Street [information](#). Once you set the preferences, the software asks you to build the index. The indexing process allows the software to make the comparison between the geographic base layer and the address file.

**Match the addresses:** You are now ready to geocode your manufacturers table. You set up the link between the geographic base file and the address field in the manufacturers table. In ArcView, you will choose View, Geocode Addresses ([see example](#)) and set up the relationship ([see example](#)). Your reference theme is the geographic base file (streets). You have already set the type of base file you are using to US Streets. Aircraft Manufacturer is the address table; you must tell the software you will use Address as the address field. You must also create a new file that will contain the point where each manufacturer is located. When you choose to match the two databases, the software takes the first record in the address table and tries to find the appropriate street ([see example](#)). It moves through each record and identifies which records are matched and which do not ([see example](#)). Notice that 73% of the address records were matched. In this example, do not worry about non-matches.

**Display the results:** The software now creates the new point data layer containing the aircraft manufacturing companies ([see results](#)). You can see that the manufacturing facilities are clustered around San Antonio International Airport and Kelly Air Force Base.

## Mastery

### Learning Objectives:

- Determine potential problems with address and reference files.
- Complete the matching process including
  - Evaluating non-matched records
  - Editing a reference file
  - Standardizing an address table
- Practical exercise: the rematch process.
- Practical exercise: creating a map using attribute information.

### Topics:

#### 1. Determine potential problems with address and reference files

- Overall problems
  - Geocoding is based on assumptions
  - addresses are in a range and equally spaced along the range
  - odd numbers are on one side of the street and evens on the other
  - places have addresses

i.e., The White House is 1600 Pennsylvania Ave

- Base file
  - Not current: i.e., streets not in file
  - Inaccurate locations
  - Incorrect or unidentified streets
  - Incorrect or unidentified address ranges
  - Inconsistent attribution i.e., I10 is also McArthur Freeway
- Address file
  - Incomplete
  - Inaccurate
  - Not standardized
- Preferences
  - Spelling sensitivity set too high or low
  - Score to be considered is too high or low

## 2. Complete the matching process

- Evaluate non-matched to determine the problem
- GBF file
  - Increase geographic area covered
  - Add new developments
- Address file
  - Standardize
- Preferences
  - Adjust index search (blocking rules)
  - Adjust matching weights (how close a match is necessary)
  - Adjust minimum score to be considered a match

## 3. Practical exercise: the rematch process

In the previous example, 73% of the address file was matched to a geographic location in the GBF. Based on the initial parameters, there was one partial match and three addresses that did not match. The rematch process allows you to evaluate why the record did not match, fix any problems, and find more matches. Non-matched records are caused by:

incorrect or incomplete address file records,  
errors or omissions in the geographic base file, or  
by setting the preferences incorrectly for the data being matched.

**Incorrect or incomplete address file records:** In the previous example, the address "10823 Northeast Entrance R" scored as a 62% match. When you look at the record compared to the GBF file, it looks like you have found a match. ([see example](#)) The software does not recognize "R" as "Road", and when the record is parsed it identifies the street name as "Entrance R" and does not identify a street type. You need to fix the incorrect address record to be "Rd" or "Road" and a match will be found. In this ArcView example, you can click on the match button to interactively match the record to the GBF.

Let's look at the unmatched records. ([see example](#)) The Alcor Aviation record is an example of an incomplete address. Colwick Street has no street number. Once a street number is entered into the database, you can rematch the record and find a match. Alternatively, you can locate Colwick interactively, see that it is a small street near the airport, and interpolate the point location. ([see example](#))

**Errors or omissions in the geographic base file:** The other two unmatched records appear to have adequate addresses. ([see example](#)) The next step is to evaluate the GBF file. You can sort the street database to show all the streets named "410". ([see example](#)) Several problems become evident. Notice that the name is inconsistent and there are no address ranges. What other problems do

you see?

Finally find all the Presa Street records. ([see example](#)) The software is looking for 9594 South Presa Street in the GBF. The highest range in the GBF file is 699 and all the Presa Streets in the database have a "N" prefix. Either the GBF file is incomplete or the address file is incorrect. You will need to do more research.

#### 4. Practical exercise: creating a map using attribute information

An aircraft manufacturing company is trying to locate interior design and manufacturing companies and propeller manufacturers in Texas. A list of these three types of companies containing addresses is obtained. ([see example](#)) You have a zip code geographic data base containing city names and zip codes. You can address geocode the file containing company addresses to this file using the zip field. ([see example](#)) Follow the three steps in the geocoding process:

- 1) prepare the data;
- 2) match the addresses; and,
- 3) display the results.

First index the zipcode file so that the software knows you are sorting by zip code. ([see example](#)) Second, identify the files to match ([see example](#)) and perform the batch match. All 47 records match. Third, display your results. ([see example](#))

You can display the propeller companies separately. In this ArcView example, make the aircraft company the active theme, and choose Edit, Copy Theme. Then choose Edit, Paste. You now have a duplicate theme. Under Theme, Properties, rename this theme "Propeller Manufacturers" and define the theme as ([Specialty] = "P"). ([see example](#)) The companies are in the Dallas/Fort Worth and San Antonio area. To see just the interior companies, make the Aircraft Companies theme active. Under Theme, Properties, define the subset as ([Specialty] = "ID") or ([Specialty] = "IP"). Then Under Theme, Edit Legend, set the Legend Type to Unique Value and the Values Field to Specialty. When you look at the interiors companies, they cluster around Dallas/Fort Worth and Houston. ([see example](#))

## Follow-up Units

Unit 40 Using reclassification operators

Unit 45 Location allocation

Unit 47 Boolean search

## Resource

### Definition of terms:

- Address geocoding: Conversion of postal addresses to geographic coordinates.
- DIME: Dual Independent Map Encoding. Predecessor to the TIGER files. Developed for the 1970 census.
- GBF: Geographic Base File. A digital geographic data base containing street networks (lines) or zip code files (point or polygon).
- Indirect georeferencing: Location of a feature based on some information (usually addresses) other than geographic coordinates (such as latitude/longitude or UTM meters). The process interpolates where the feature will be placed based on a reference file and a matching strategy.
- Reference files: A GBF used in the address geocoding process to indirectly reference a table of addresses to geographic coordinates.
- SIC Standard Industrial Classification A grouping of industries, classified by a government, usually with major grouping and sub-codes.
- Table of addresses: A database containing an address field and, usually, other attribute information.
- TIGER: Topologically Integrated Geographic Encoding and Referencing. A digital geographic data layer of streets and other census boundaries, created by the U.S. Bureau of the Census to support U.S. Census operations.

### Reference Material:

- An excellent list of reference print and web references is found in (Unit 016 NCGIA Core Curriculum in GIScience: Discrete GeoReferencing, section 7)

## Review and study guide

1. What are the three components necessary for address geocoding?
  - Geographic base file
  - Address file
  - Software
  
1. What should you consider when beginning a geocoding application?
  - Level of detail in address file (i.e. just zip code, full address, accuracy of the database)
  - Accuracy of the geographic database and whether you need to use more than one (i.e. streets for full street addresses, zip codes for rural routes)
  - Purpose of the application
  
1. Describe the basic process used by the software to find locate a US street address.
  - Finds the address in the address file
  - Parses the address out based on the rules selected by the operator
  - Locates the street based on the blocking strategy selected
  - Determines the side of the street
  - Interpolates where the address is located on the street
  - Places the point
  
1. Create an attribute table for a geographic base file that contains the correct fields for the US Streets address style.

2. What field is necessary in the address reference file? Describe its characteristics?
  - Any field containing an address
  - Entire address is in one field (i.e. 125 Spring Valley Loop)
  - Name some problems you can encounter with address files?
  - Standardization not considered when designing and populating the database
  - Inconsistencies
  - Incomplete information (i.e. 125 Valley Rd. should be 125 N. Valley Rd.)
  - Multiple spellings of same place
  - Rural routes and P.O. boxes
  
1. How do you correct the problems?

- Standardize database prior to address matching
  - US Postal Service standardization
1. What problems might you find in the geographic base file?
    - Location inaccurate
    - New subdivisions not included: database not current
    - Inaccurate attributes (i.e. wrong street names)

Displays a dialog box to create a geocoded theme

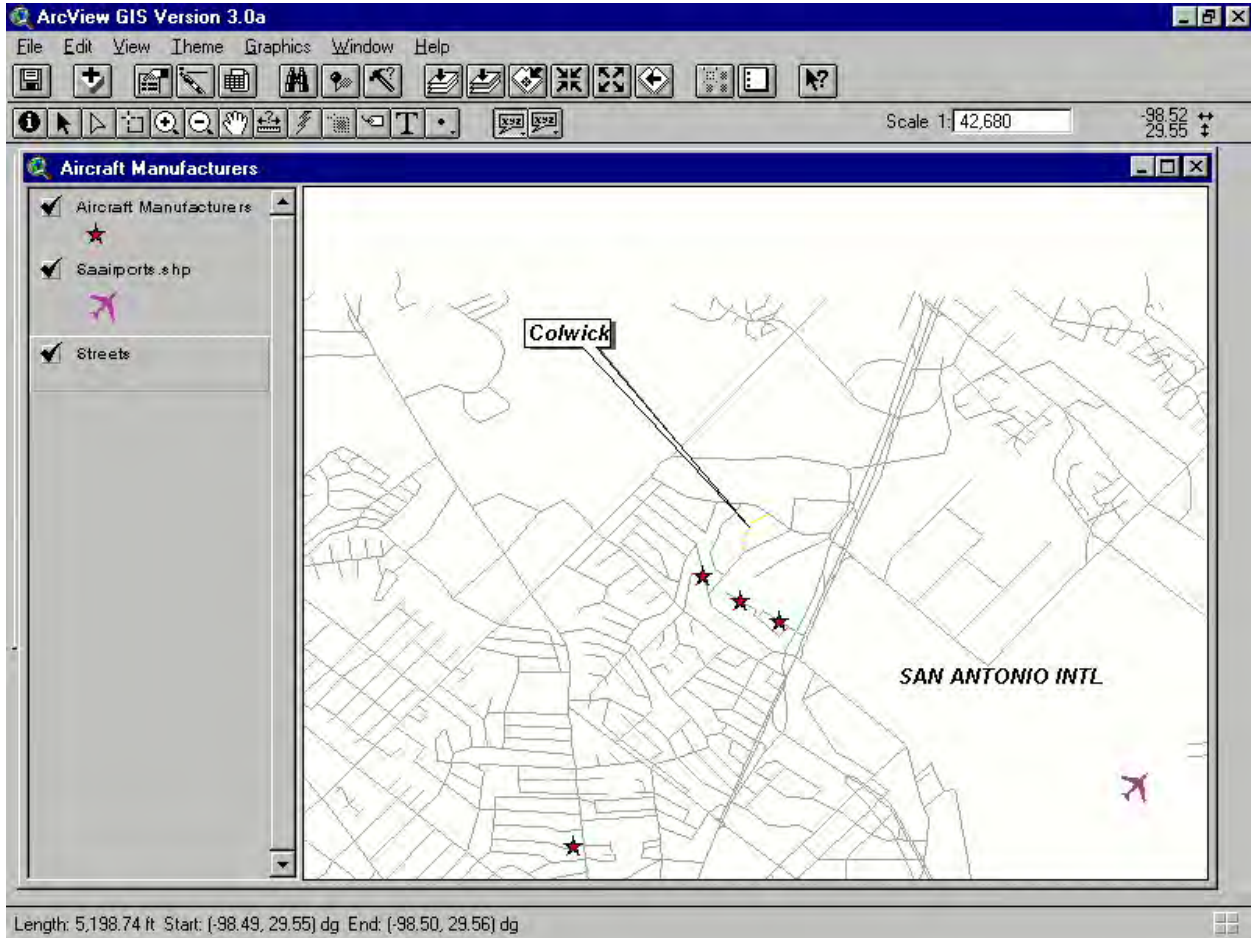

The screenshot shows the ArcView GIS interface. The main window displays a map of San Antonio with several red star markers. A table titled "Attributes of Aircraft Manufacturers" is overlaid on the map, showing a list of companies and their addresses. The table has columns for various attributes including status, score, side, shape, company name, address, city, and state.

<i>Av status</i>	<i>Av score</i>	<i>Av side</i>	Shape	<i>Company</i>	<i>Address</i>	<i>City</i>	<i>State</i>
