Objective—Exercise is vital for maintaining cartilage integrity in healthy joints. Here we examined the exercise-driven transcriptional regulation of genes in healthy rat articular cartilage to dissect the metabolic pathways responsible for its potential benefits.

Methods—Transcriptome-wide gene expression in the articular cartilage of healthy Sprague-Dawley female rats exercised daily (low intensity treadmill walking) for 2, 5, or 15 days was compared to that of non-exercised rats, using Affymetrix GeneChip arrays. Database for Annotation, Visualization and Integrated Discovery (DAVID) was used for Gene Ontology (GO)-term enrichment and Functional Annotation analysis of differentially expressed genes (DEGs). Kyoto Encyclopedia of Genes and Genome (KEGG) pathway mapper was used to identify the metabolic pathways regulated by exercise.

Results—Microarray analysis revealed that exercise-induced 644 DEGs in healthy articular cartilage. The DAVID bioinformatics tool demonstrated high prevalence of Functional Annotation Clusters with greater enrichment scores and GO-terms associated with extracellular matrix (ECM) biosynthesis/remodeling and inflammation/immune response. The KEGG database revealed that exercise regulates 147 metabolic pathways representing molecular interaction networks for Metabolism, Genetic Information Processing, Environmental Information Processing, Cellular Processes, Organismal Systems, and Diseases. These pathways collectively supported the complex regulation of the beneficial effects of exercise on the cartilage.

Conclusions—Overall, the findings highlight that exercise is a robust transcriptional regulator of a wide array of metabolic pathways in healthy cartilage. The major actions of exercise involve ECM biosynthesis/cartilage strengthening and attenuation of inflammatory pathways to provide prophylaxis against onset of arthritic diseases in healthy cartilage.

Introduction

Exercise is vital for maintaining cartilage integrity/homeostasis in healthy joints¹⁻⁴. However, the mechanistic details of its actions on healthy cartilage remain elusive. Here, our objective was to examine the exercise-driven regulation of gene expression and consequent metabolic pathways that are responsible for its benefits on healthy cartilage.

Exercise/physical activity transcriptionally activates/inhibits genes associated with various cellular functions in cartilage⁵⁻⁸. Chondrocytes within the cartilage are mechanosensitive cells that can perceive and respond to mechanical signals by regulating molecular networks. These cells synthesize glycosaminoglycans (GAGs) and collagen type II-rich extracellular matrix (ECM) that are essential for the maintenance, strengthening, and regeneration of healthy cartilage⁹⁻¹². During inflammation, upregulation of proinflammatory genes compromises the ability of chondrocytes to synthesize ECM, leading to loss of cartilage integrity, initiation of cartilage destruction, and onset of osteoarthritis (OA)¹³⁻¹⁵. Adequate exercise has been shown to be beneficial in human and experimental OA: regular aerobic exercise decreases plasma and articular levels of cytokines and their receptors, decreases pain and increases mobility of joints in OA patients and in experimental models of OA^{5, 16, 17}.

In addition to its positive effects on inflamed joints, exercise is considered to be an anabolic therapy for healthy cartilage. Exercise is shown to increase GAG contents in synovial fluids

and plasma, improve joint function and muscle performance, and delay joint symptoms in patients with high risk of OA^{5, 18}. Nevertheless, there is a clear paucity of mechanistic studies on the molecular networks/metabolic pathways regulated by exercise in healthy joints, which eventually prevents onset of arthritic diseases. This knowledge gap has limited our ability to exploit the therapeutic potential of exercise and maximize its effectiveness in healthy subjects. Understanding the exercise-mediated mechanisms of actions on cartilage would allow identification and functional understanding of key molecules that could be developed as tools to measure exercise effectiveness, and also to develop precisely targeted exercise regimens for both healthy individual and for those at risk of OA. For example, genome wide association studies (GWAS) have recently identified several genes associated with human OA^{19–21}. Whether exercise prevents expression of these genes and thus onset of OA is as yet unknown, but this knowledge is critical for the prevention and physiotherapeutic management of OA.

In this study, we utilized a rat model to examine the effects of exercise on healthy articular cartilage. The advantages of this model were that rats could easily be trained to exercise on treadmills, provided sufficient cartilage for analysis from individual specimens, and were relatively docile in cages. The transcriptome-wide microarray analysis followed by analyses with bioinformatics tools, Database for Annotation, Visualization and Integrated Discovery (DAVID) v6.7 and Kyoto Encyclopedia of Genes and Genome (KEGG) pathway mapper demonstrated that exercise transcriptionally activates/represses $2.6\% \pm 0.17\%$ of the entire transcriptome of rat femoral cartilage, driving 147 discrete but interdependent metabolic pathways^{22–25}. More importantly, the major metabolic pathways regulated by exercise are associated with ECM biosynthesis and inflammation/immune responses in healthy cartilage, including those that are associated with OA^{19, 20}.

Materials and Methods

Experimental Design

The study was conducted according to guidelines for the Use of Laboratory Animals in Research and was approved by the Institutional Animal Care and Use Committee at The Ohio State University (#2009A0138-R2). Healthy Sprague Dawley rats (n=20 rats, 5/group, 12–14 week-old females, 250–300 grams, Harlan Labs, IN) were housed as three animals/cage in individually ventilated cages with sterile Aspen bedding, and standard environmental enrichment. The cages were maintained at 12-h light/12-h dark cycle at 21°C in a pathogen free unit. All rats had ad libitum access to water and food and were allowed normal cage activity. All rats were trained to walk on treadmills for 3 days to exclude untrainable animals. Fifteen days following the training, animals randomly assigned to each group and were either not exercised (Controls) or subjected to low intensity exercise between 8–11 AM daily (treadmill walking, 12 m/min, 45 min/day) for 2, 5, or 15 days. Three hours following the last exercise regimen, animals were euthanized by CO₂ asphyxia²⁶. Full thickness articular cartilage from the distal femoral heads of both legs was carefully dissected on ice under a stereomicroscope (10–15 mg/femur), and immediately placed on dry ice and pulverized (3×30 seconds at 2500 RPM) in a Mikrodismembrator S (Sartorius, Germany). The cartilage from individual rats was analyzed separately. RNA was extracted using Trizol

reagent (Invitrogen, CA), and RNA quality was verified by a Bioanalyzer 2100 (Agilent, CA)¹³. The Whole Transcript (WT) cDNA Synthesis and Amplification Kit and WT Terminal Labeling Kit (Affymetrix, CA) were used for cDNA synthesis and labeling from 300 ng RNA template as recommended by the manufacturers. Labeled samples from three different rats from each group were hybridized to Affymetrix GeneChip Rat Gene 1.0 ST Arrays and gene chips scanned with GeneChip Scanner 3000 7G System (Microarray Shared Resource Facility, OSU Comprehensive Cancer Center)¹³.

Identification of DEGs

Partek Genomic Suite version 6.4 software (Partek Inc., MO) was used to analyze intensity scans from three independent rats per group. The normal distribution of the overall gene expression was confirmed by the histogram showing data distribution within three Σ with the kurtosis and skewness z values within |2| (Supplementary Fig. S1). Principal Component Analysis (PCA) was used to confirm expression uniformity within each group and the data were subjected to both hierarchical and partition clustering by Partek Genomic Suite [Fig. 1(A,B)]. As compared to non-exercised controls, the DEGs showing either up- or down-regulation of a specific gene on all three days, with +2.0 or -2.0 fold or greater change on one or more days were included for the biological interpretation of the exercise-driven molecular/metabolic networks [Fig. 1(C), Tables I,II]. The raw microarray data has been deposited in a MIAME compliant database GEO (accession number GSE74898).

Validation of salient genes differentially expressed in microarray analysis

The expression of select DEGs from microarray analysis was confirmed by quantitative real time polymerase chain reaction (qrt-PCR)²⁶. Briefly, RNA samples (n=5/group, including samples used in microarray analysis) were subjected to qrtPCR analysis. Extracted RNA was subjected to first strand cDNA synthesis using the Superscript III Reverse Transcriptase Kit (Invitrogen, CA). Gene expression was assessed by amplifying the cDNA with commercially obtained primers (Qiagen, MA) or are provided in Supplementary Table S1. The mRNA levels were calculated by normalizing to GAPDH using Ct method.

Functional Annotation and molecular network analysis

To assess biologic relevance, the data set obtained from rats exercised daily for 15 days was compared to non-exercised rats using GO analysis. DAVID Gene ID conversions tool was used to identify *Rattus norvegicus* gene IDs. GO screening and Functional Annotation Clustering were performed by DAVID Bioinformatics tool v6.7 [<http://david.ncifcrf.gov/home/jsp>; GOTERM_BP_FAT (biological process); GOTERM_MF_FAT (molecular function); GOTERM_CC_FAT (cellular component)]^{22, 23}. KEGG Pathway mapper (<http://www.genome.jp/kegg/pathway.html>) was used to reveal the higher-order biological functions and metabolic pathways regulated by exercise^{24, 25}. The pathway terms identified by KEGG Mapper containing two or more DEGs were included in the analysis. Both the *kgml* format downloaded from KEGG website and the manual search function in the online pathway maps were used.

Statistical Analysis

The statistical significance of the differences in the microarray data between control cartilage and experimental cartilage from rats exercised for 2, 5 or 15 days was tested by ANOVA using Partek genomic suit (n=3 independent sample/group) and only significantly regulated transcripts ($p<0.05$) were further analyzed. SPSS v17 was used to determine the significance levels of qrtPCR data (n=5/group) by ANOVA with Tukey's honest significant difference post hoc test. The data is expressed as the mean \pm standard error of the mean (SEM), with $p<0.05$ regarded as significant.

Results

Temporal regulation of gene expression by exercise

All experimental animals remained healthy without adverse effects from exercise, and little change in weights ($\pm 2\%$). The transcriptome wide microarrays analysis identified a pool of DEGs in cartilage from rats subjected to daily exercise for 2, 5, or 15 days, in comparison to non-exercised controls (n=3 out of 5 animals/group). PCA analysis of the DEGs revealed relatively uniform distribution of overall global gene expression in the samples following 2 or 5 days of daily exercise as compared to non-exercised controls. However, differences in gene expression on day 15 were observed, as demonstrated by the average F ratio (signal to noise ratio) of 18.8 [Fig. 1(A)]. Hierarchical clustering analysis of the differentially regulated genes ($p<0.05$) indicated temporal regulation of distinct sets of genes following each day of exercise [Fig. 1(B)]. A total of 27,342 transcripts were detectable by the Affymetrix Rat GeneChip arrays. Following exclusion of predicted/ambiguous *Rattus norvegicus* genes, the DAVID gene ID conversion tool revealed that in comparison to controls, 774 (2.8%), 677 (2.5%), and 644 (2.4%) of the transcripts were differentially and significantly ($p<0.05$ for each gene) up- or down-regulated by more than 2-fold on days 2, 5, and 15, respectively. Therefore, 644 DEGs from day 15 dataset that were similarly/consistently regulated by exercise on days 2, 5 and 15, were selected for further analysis [Fig. 1(C)]. Among 644 DEGs from the day 15 dataset, 254 transcripts were upregulated and 428 transcripts were downregulated by exercise [Fig. 1(C)], and were subjected to DAVID database and KEGG pathway mapper to investigate the overall exercise-dependent modification in the molecular networks in the articular cartilage.

The quantification of the DEGs by qrtPCR demonstrated results that were consistent with microarray analysis, albeit the magnitudes were often higher than those observed in the microarray analysis. The RNA samples (n=5/group, inclusive of those used in microarray analysis) were analyzed by qrtPCR for genes from ECM synthesis/(*Fgf2*, *Cilp*, *Cyt11*) remodeling (*Mmp8*, *Mmp9*, and *Mmp3*) and inflammation (*Ptgs2*, *Lyz*, and *Hmgb2*) categories [Fig. 1(D)].

DAVID GO-term Functional Annotation Enrichment Analysis

The GO Clustering of 644 DEGs provided a preliminary description of the potential functions of DEGs and their effects on cells. The GO terms with at least 2 genes and false discovery rate (FDR) of $<1.0E-03$ as significance threshold were selected to perform Functional Enrichment Analysis. This analysis generated 86 clusters with enrichment scores

from 10.33 to 0.99 and GO-terms associated with GOTERM_MF_FAT, GOTERM_BP_FAT, and GOTERM_CC_FAT. These annotation clusters contained GO-terms enriched in inflammation/inflammatory responses, signal transduction and ECM biosynthesis/regulation [Fig. 2(A,B,C)]. Additional GO-terms in these clusters were associated with responses to cell division/differentiation/growth, intermediate metabolism, muscle function/differentiation, cell motility/migration, cell adhesion/communication, ion channel regulation, cytoskeletal organization, extracellular communication, and bone development/mineralization.

KEGG pathway analysis of molecular interaction and reaction networks

Further interpretation of the higher-level systemic functions of the 644 DEGs (superimposed on the *Rattus norvegicus* (rno) reference pathway) by KEGG mapper demonstrated that exercise regulated a total of 147 metabolic pathways in the articular cartilage, 93 pathways at cellular levels and 54 at the organismal level (Tables I, II)^{24, 27}. Only pathways with two or more DEGs were included in this analysis. Exercise regulated a wide array of metabolic pathways representing the KEGG defined molecular interaction and reaction networks as follows:

- i. *Metabolism*. Exercise regulated pathways involved in intermediate metabolism, such as synthesis of carbohydrates, energy, lipids, nucleotides, amino acids, glycans, co-factors/vitamins, terpenoids/polyketides, and xenobiotics.
- ii. *Genetic Information Processing*. While exercise regulated pathways involved in DNA repair, translation, folding, sorting and degradation of proteins, and DNA repair, it suppressed DNA replication pathways. For example, exercise suppressed several genes integrally associated with the cell cycle such as *S100a9* and cyclins, the regulators of the cell cycle and mitosis. Furthermore, *Igf1*, *Igf1bp6* and *Pdgfb*, growth factors important in the regulation of cell division, were also suppressed^{28, 29}.
- iii. *Environmental Information Processing*. Surprisingly, exercise upregulated *Per2*, *Cry1* and *Cry2* genes that regulate circadian rhythms³⁰.

Another major target regulated by exercise was signal transduction pathways and interactions of signaling molecules, where exercise regulated 31 different signaling cascades. Furthermore, DEGs regulating PI3K, Ras, MAPK, Rap-1, cAMP, sphingolipid, cGMP, NF-kB, and FoxO signaling cascades were markedly over represented in comparison to other metabolic pathways (Table I). Activation of these signaling pathways by exercise in turn regulated multiple cellular processes. For example, exercise regulated PI3K-AKT signaling, which showed association with 18 different signaling cascades regulated by DEGs *Bcl2*, *Fgf3*, *Fgf14*, *Fgf2*, *Gng11*, *Hsp90*, *Itga5*, *Prkca*, *IL-1*, and *Thbs2* (Fig. 3).

- iv. *Cellular Processes*. Exercise regulated pathways that control cellular transport and catabolism including such activities as Fc-gamma mediated phagocytosis, endocytosis, and lysosome and peroxisome functions. Exercise also regulated

cell motility, growth and death, and cell communication by regulating the actin cytoskeleton, cell cycle, apoptosis, cell adherence and cell junctions.

- v. *Organismal Systems.* Surprisingly, exercise regulated many of the pathways involved in organismal functions in cartilage. For example, exercise regulated more than 20 pathways in immune (soluble and cellular immune responses), 11 in endocrine (renin-angiotensin, insulin, thyroid stimulating hormone, lipolysis, etc), 8 in digestive (protein, fat, carbohydrate absorption, digestive secretions), 8 in nervous (long term depression, several synapses,), 3 in circulatory (smooth & cardiac muscle contraction) systems, 2 in sensory (inflammatory mediator regulation, olfactory transduction), development (osteoclastogenesis), and environmental adaptation (circadian entrainment) (Table II).
- vi. *Human Disease.* KEGG mapper also revealed that exercise regulated genes associated with diseases, likely due to involvement of signaling cascades, growth factors and metabolic pathways. We did not explore these genes in detail, but a list of these diseases and pathways is provided in Supplementary Table S2.

Examination of Major Exercise-Driven Pathways in Cartilage

Functional Annotation Clusters identified a preponderance of GO-terms enriched in immune responses, signal transduction and ECM [Fig. 2(A)]. Similarly, KEGG mapper demonstrated exercise-dependent regulation of glycan biosynthesis and inflammation/immune responses (Tables I, II). Since signal transduction pathways are common in many pathways regulated by exercise, we next focused on cartilage specific pathways involved in ECM biosynthesis and immune response. Furthermore, the manual search function in the online pathway maps was used to identify DEGs involved in ECM biosynthesis and immune responses.

ECM biosynthesis and metabolism

Interestingly, DAVID database revealed that the most highly enriched functional clusters contained GO-terms associated with ECM biosynthesis. These GO-terms also contained greater numbers of DEGs than other clusters. These DEGs were involved in GO-terms representing major biosynthetic functions of chondrocytes, such as peptide secretion, ECM synthesis, inhibitors of peptidases, response to mechanical forces, GAG synthesis, peptidases, metalloproteases, etc [Fig. 2(B)]. Similarly, manual examination also demonstrated that exercise upregulated DEGs required for biosynthesis of ECM, and inhibitors of ECM degrading enzymes, but suppressed proteolytic enzymes and non-cartilaginous proteins. For example, exercise upregulated DEGs involved in ECM biosynthesis such as *Dcn*, *Cilp*, *Eln*, *Vcan*, *Chst1*, *Chst3*, *Hs3st1*, *Cyt11* (proteoglycan synthesis), and *Fgf2*, while suppressing non-cartilaginous genes such as *Col24a1* (fibrillogenesis), *Col9a2*, *Col9a3* (fibrillar collagen), *Col1a2* (bone collagen), *Ctsk* and *Post* (bone), *Tnn* (nerve protein), *Matn3* and *Matn4* (unknown function) (Table III). Additionally, exercise suppressed synthesis of matrix-metalloproteinases (*Mmp8*, *Mmp9*, *Mmp14*), and proteoglycanolytic enzymes (*Adamts3*, *Adamts14*) involved in ECM degradation (Table III) and upregulated gene expression for inhibitors of proteolytic enzymes such as *Timp4*,

Serpina1, *Serpina3n*, *Mug1*, *Mug2*, and *Agt*. Furthermore, *Serpinb1a*, *Serpinf1*, and *Serpinb6b*, clotting factors thrombin and kallikrein, and serine proteases were all suppressed during the entire 15 days of exercise regimens [Fig. 2(B)], Table III).

Immune Function

DAVID functional enrichment analysis revealed that at least 187 GO-terms enriched in 12 different functional annotation clusters were associated with immune function, indicating that this was the most exercise-regulated function in chondrocytes [Fig. 2(C)]. The GO-terms in these functional annotation clusters were associated with defense response, cytokine activity, chemotaxis, B cell regulation, regulation of ossification, antigen processing, leukocyte proliferation, immune effector mechanisms, phagocytosis, acute inflammatory response, innate immune response, defense response to virus, and antimicrobial activity, further indicating that exercise regulated diverse aspects of inflammation/immune responses [Fig. 2(C)]. KEGG pathway mapper also indicated that exercise regulated 20 different inflammation/immune response (both soluble and cellular components) associated pathways and 14 different signaling pathways that regulate immune responses (Tables I, II). The DEGs showed that exercise upregulated decoy receptors *Il6ra* and *Il1r2*, blocking cellular responses to cytokines IL-6 and IL-1; *Cxcl13*, a chemokine that localizes B cells in follicles; *IL-16*, a chemoattractant and an inhibitor of HIV replication; *Thbs2*, a thrombospondin with anti-angiogenic properties, and *Lbp* in Toll-like receptor signaling pathway. Exercise also induced DEGs encoding protease inhibitors (*Agt*, *Mug1*, *Mug2*, *Cpvl*, *Serpina1*, *Serpina3n*), and clotting factors (*Thbs2* and *Plat*), while suppressing gene expression for *C3* and *C7*, chemokine receptors *Ccr1*, *Cxcl12*, and enzymes involved in prostaglandin/lipoxygenase synthesis *Ptgs2*, and *Alox15*. Additionally, exercise activated and deactivated *Pde3a*, *Pld5*, *Plce1*, *Pla1a*, *Pde3b*, *Pla2g2a*, enzymes involved in hydrolysis of phospholipids in response to cytokine and endotoxin signaling pathways, such as *PI3K-AKT*, *NF-κB*, *Ras*, *Rap*, *MAPK*, *cAMP*, and *Ptgs2* (Table IV).

Exercise Regulates OA associated genes

The observations that exercise suppresses proinflammatory pathways led us to investigate whether our dataset includes human OA-associated genes identified by HuGe Navigator^{19, 21, 31}. Indeed, several OA-associated DEGs were regulated by exercise in healthy cartilage. For example, exercise suppressed expression of genes upregulated in OA such as *Ptgs2*, *Mmp9*, *Mmp8*, *Igf1*, *Colla1*, *Adamts3*, *Adamts14*, and *Vdr*, which encode proteins involved in ECM degradation, bone formation, and initiation of pro-inflammatory cascades. Conversely, exercise upregulated many of the genes involved in ECM synthesis that are downregulated in OA such as *Chrdl2*, *Tnfrsf11b*, *Timp4*, *Thbs2*, *Tgfb1*, *Mmp3*, *Il1r1*, *Il1r2Cilp* and *Bmp5* (Fig. 4; Supplementary Table S3).

Discussion

We demonstrate for the first time that low intensity exercise is a potent transcriptional activator/repressor of genes that are involved in improving overall cartilage health and contributes to prophylaxis against inflammation, such as those observed during onset of OA. Since conducting studies on healthy human cartilage is not possible, here we used rats as an

experimental model. The full thickness articular cartilage provided an ideal tissue to critically analyze the complex exercise-driven gene-regulation *in vivo*, specifically in chondrocytes without interference of other cell types^{12, 32}. Furthermore, because immobilization itself alters gene expression, cartilage from non-exercised rats with normal cage activity provided a suitable control for comparing DEGs in exercised rat cartilage³³. The Affymetrix-gene-chip analysis of articular cartilage followed by DAVID gene ID conversions demonstrated that as compared to non-exercised controls, daily exercise differentially and significantly regulated 2.6%±0.17% of the genes in the entire transcriptome: 774 DEGs on day 2, 677 DEGs on day 5, and 644 DEGs on day 15. Furthermore, exercise consistently up- or down-regulates the same 644 DEGs at each time point, indicating that these genes are likely crucial for its actions in cartilage. Therefore, these DEGs from day 15 dataset were selected for biological interpretation of their higher level systemic functions.

A major function of chondrocytes is to maintain the homeostasis of ECM for mechanical support of the joints^{12, 32}. The functional annotation clustering of these GO-terms further confirmed that exercise regulates a wide range of cellular functions. However, the prevalence of functional clusters and their higher enrichment scores associated with ECM biosynthesis/remodeling and immune response identified that a major consequence of exercise is maintenance of cartilage integrity.

The regulation of 147 metabolic pathways in KEGG pathway analysis demonstrated that exercise regulates a wide range of chondrocyte functions sub-categorized as those involved in intermediate metabolism, genetic information processing (functional regulation of RNA/DNA), environmental information processing (perceiving and responding to extracellular stimuli, physical and biochemical), cellular processes (cellular functions such as transport, growth, apoptosis, communication), organismal systems (regulation of various body functions), and diseases. Interestingly, exercise regulated as many as 33 or as few as 2 DEGs (Tables I,II) in these pathways to control their activation/suppression. Moreover, many of these DEGs regulated more than one metabolic pathway at both cellular and organismal levels. For example, exercise regulated PI3K-AKT pathway which in turn regulates 18 different pathways including glycolysis, cell cycle, NF-κB and p53 metabolic pathways, revealing the complexity of the gene regulation by exercise (Fig. 3).

The KEGG mapper also demonstrated that exercise upregulates biosynthesis of the basic building blocks of proteoglycans, GAGs including hyaluronan, keratan sulfate, chondroitin sulfate, heparan sulfate, and dermatan sulfate, glycosphingolipids and proteases that are involved in the degradation of GAGs. Similarly, manual identification of DEGs demonstrated that exercise-induced biosynthesis of ECM structural proteins, growth factors (*Fgf2*, *Fgf13*, and *Fgf14*), and signaling molecules, while inhibiting expression of non-cartilaginous DEGs (*Col9a2*, *Col9a3*, *Col1a2*, and *Ctsk*)^{29, 31, 34–38}. In fact, exercise negatively regulated expression of enzymes involved in ECM degradation, while upregulating expression of inhibitors of proteases involved in ECM degradation (*TIMP14*, *Serpina 1*, *Serpina 3a*, and *Mug1 & 2*)³⁹. Thus our findings support the earlier observations that exercise strengthens healthy joints, and further provide molecular evidence that exercise activates metabolic pathways critical for maintaining ECM production, limiting cartilage

destruction and maintaining the cartilage-specific tissue phenotype to protect its integrity and structural strength^{1, 40–42}.

The second major function demonstrated by the functional annotation clusters with more than 187 GO-terms were enriched in functions associated with inflammatory and immune responses (Fig. 2). These GO-terms and clusters also suggested that exercise regulates both soluble and cellular components of the immune system. KEGG pathway analysis also demonstrated that exercise regulates at least 20 different pathways involved in inflammation/immune function (Table II). Exercise is shown to be anti-inflammatory and to suppress proinflammatory gene induction in inflamed cartilage *in vivo* and *in vitro*^{7, 10, 11, 43, 44}. Our data further demonstrates that exercise also significantly controls these pathways in healthy cartilage. However, many of the genes regulated by exercise in an inflammatory state are distinct from those regulated by exercise in healthy cartilage^{26, 44–47}. For example, exercise in inflamed cartilage directly attenuates NF- κ B activity to suppress induction of cytokines (*Il1 β* , *Tnfa*, *Il8*) and matrix-metelloproteinases. In healthy cartilage exercise upregulates soluble/decoy receptors for cytokines and chemokines, their receptor antagonists (*Il6ra* and *Il1r2*, and cytokine-cytokine receptor interactions, chemokines that regulate lymphocytes mobility (*Cxcl13*, localizes B cells in follicles, and *Il16*, a chemoattractant for CD4+ cells), and genes encoding protease inhibitors (*Agt*, *Mug1*, *Mug2*, *Cpvl*, *Serpina1*, *Serpina3n*, and *Plat*). Exercise downregulates Toll-like receptor-4 (*Tlr4*) expression in circulating lymphocytes^{10, 11, 48}. Our data demonstrates that exercise suppresses ligands for TLRs (*Hmgb2* and *S100a8*) in TLR signaling pathway. Strikingly, exercise prevents blood clot formation by upregulating *Plat* but suppressing *F5*, limits expression of complement components (*C1qr1*, *C3* and *C7*), chemokines and their receptors (*Ccr1* and *2*, *Cxcr4*, *Cxcl12*), neutrophilic proteins (*Defa*, *Lyz*, *Npg*), and the major proinflammatory enzymes *Ptgs2* and *Alox15* to inhibit production of prostaglandin and leukotrienes to collectively suppress major inflammatory cascades^{49, 50}. These observations suggest that exercise-mediated negative regulation of pathways for proinflammatory signaling may be a powerful mechanism to protect cartilage from inflammation and onset of arthritic diseases.

Analysis of DEGs demonstrated that exercise suppresses expression of several genes in healthy cartilage that are upregulated in OA such as pathways involved in ECM degradation, activation of proinflammatory signaling cascades, genes that code for non-cartilaginous proteins and the genes associated with osteoclast activation. Correspondingly, exercise upregulates several genes that are beneficial for ECM synthesis but are suppressed in OA (Fig. 4). This differential regulation of genes explains the putative beneficial effects of exercise in preventing/delaying the onset and progression of OA.

Although our studies have provided an overall mechanistic view of the metabolic changes induced by exercise, we have used the entire femoral cartilage without distinguishing between load-bearing and non-load-bearing sites. Nevertheless, both exercised and non-exercised control rats were allowed normal cage activity, except for 45 minutes/day of exercise in the experimental groups, therefore all differences in gene expression between groups can be attributed to exercise. Furthermore, it may be challenging to extrapolate these findings to humans due to biomechanics during walking. However, the fact that normal homeostasis was maintained in the rats with applied low intensity exercise suggests that this

amount of loading was appropriately analogous to the humans, where moderate walking exercise in a healthy joint promotes homeostasis of the healthy joints.

In conclusion, on the molecular basis, we have demonstrated that exercise is a robust approach to preserve healthy cartilage. Exercise regulates the metabolic responses at both cellular and systemic levels to interdependently synchronize a wide range of anabolic pathways that are important in protecting cartilage strength and phenotype. More importantly, exercise provides prophylaxis against OA by potentially altering expression of genes involved in its onset. Thus, the findings identify a sophisticated regulatory paradigm whereby exercise synchronizes numerous gene regulatory networks to ensure cartilage health and prevent onset of arthritic diseases.

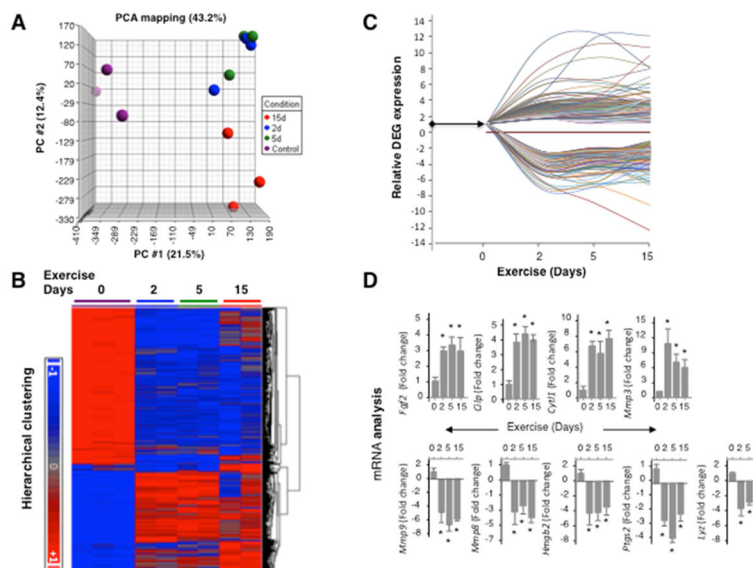

Fig. 1. Regulation of transcriptome-wide gene expression by exercise

The rats were either not exercised or exercised daily for 2, 5 or 15 days. Subsequently, the differentially expressed genes (DEGs) in the distal femoral cartilage were identified by transcriptome-wide microarray analysis. (A) Principal component analysis demonstrating overall gene expression levels in non-exercised control rats and those subjected to daily exercise for 2, 5 or 15 days ($n=3/\text{group}$) and relatively uniform distribution of the datasets within each group. (B) Hierarchical clustering of the transcripts that were significantly ($p<0.05$) and differentially up- or down-regulated by more than two-fold at one or more time points. The cluster map represents the gene expression profiles of the articular cartilage from exercised rats compared to non-exercised rats, demonstrating that distinct gene sets were temporally regulated during each day of exercise. (C) Exercise-driven regulation of transcripts that were, as compared to controls, differentially and significantly ($P<0.05$) up- or down regulated on days 2, 5, or 15, with $+2.0$ or -2.0 fold or greater change on one or more days. Out of the 644 DEGs that were similarly/consistently regulated by exercise 254 were up- and 428 were down-regulated. Arrow indicates control value of each DEG. (D) Validation of exercise-driven DEGs by qrt-PCR of salient genes associated with ECM biosynthesis (*Fgf2*, *Cilp*, *Cyt1l*) and remodeling (*Mmp3*, *Mmp9*, *Mmp8*), and inflammation (*Hmgb2*, *Ptgs2*, *Lyz*). The levels of amplification of these genes in microarray analysis are indicated by * in Tables III & IV. The data in graphs represents mean \pm standard error of the mean (SEM). Significant differences with respect to Control are indicated by * ($P<0.05$ by Tukey's post hoc test).

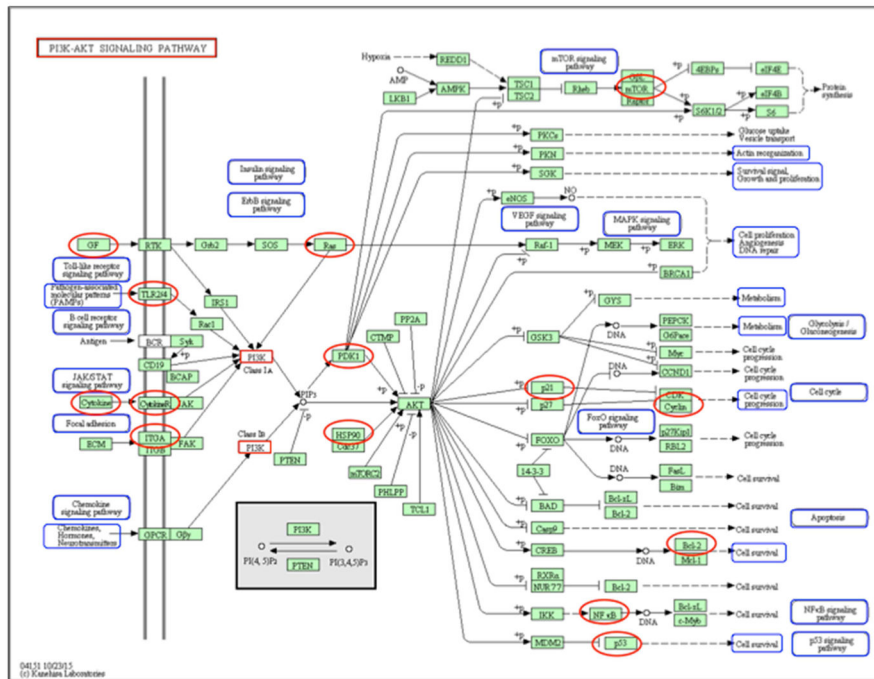

Figure 3. KEGG map displaying regulation of exercise-driven pathways via PI3K-AKT signaling cascade

The metabolic map of PI3K-AKT signaling cascade demonstrating potential points regulated by exercise, providing an example of interdependent regulation of signaling cascades by exercise. The blue rectangles highlight the KEGG identified pathways that are regulated by exercise. Red ovals indicate the DEGs regulated by exercise. Pathways and genes that are regulated by exercise in each pathway are provided in Table I.

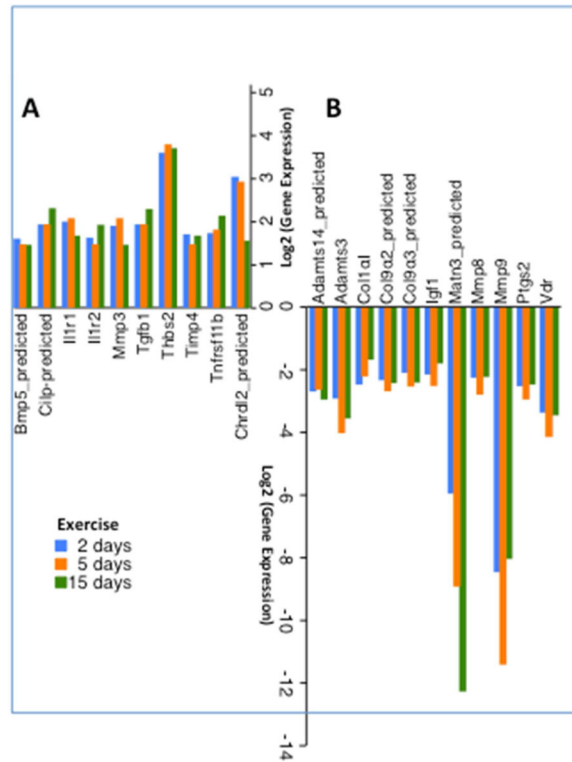

Figure 4. Regulation of OA associated genes by exercise in healthy cartilage

The dataset from microarray analysis was examined for the exercise-driven regulation of OA candidate genes identified by Human Genome Epidemiology Navigator from GWAS. The graphs show (A) genes that are suppressed in OA and show upregulation by exercise in healthy cartilage, and (B) genes that are upregulated in OA and are suppressed following exercise in healthy cartilage.

TABLE I

KEGG pathway analysis of intracellular pathways regulated by exercise in healthy articular cartilage.

Alpha-2-macroglobulin	<i>A2m</i>	1	-2.17	-2.13	-2.47	
Inhibitors of ECM Degradation		Gene symbol	Day 0	Day 2	Day 5	Day 15
Cathepsin K	<i>Ctsk</i>	1	-2.86	-3.58	-2.48	
ADAM metalloproteinase thrombospondin type1 motif, 3	<i>Adamts3</i>	1	-3.00	-4.36	-4.98	
* Matrix metalloproteinase 8 (neutrophil collagenase)	<i>Mmp8</i>	1	-2.42	-3.17	-2.37	
Dipeptidyl-peptidase 4	<i>Dpp4</i>	1	-3.81	-3.87	-4.03	
* Matrix metalloproteinase 9 (gelatinase B)	<i>Mmp9</i>	1	-8.20	-11.32	-7.84	
ADAM metalloproteinase thrombospondin type1 motif, 14	<i>Adamts14_pred</i>	1	-2.47	-2.36	-2.47	
ADAM metalloproteinase thrombospondin type1 motif, 3	<i>Adamts3</i>	1	-2.48	-3.90	-3.31	
* Matrix Metalloproteinase 3	<i>Mmp3</i>	1	2.06	2.13	1.53	
Matrix Metalloproteinase 14	<i>Mmp14</i>	1	-1.92	-2.50	-2.02	
Heparanase	<i>Hpse</i>	1	1.27	1.05	2.01	

Footnote: Salient transcripts showing two fold or greater up- or down-regulation of DEGs following 2, 5, or 15 days of exercise as compared to unexercised controls.
 * Represents genes analyzed by microarray analysis for comparison with qrtPCR dataset in Fig 1D.

Table IV

Temporal regulation of inflammation/immune system associated transcripts by exercise.

Gene name	Gene symbol	Day 0	Day 2	Day 5	Day 15
Chemokine (C-X-C motif) ligand 13	<i>Cxcl13</i>	1	2.25	4.37	9.85
Interleukin 16	<i>Il16</i>	1	2.62	3.07	2.69
Interleukin 1 receptor, type II	<i>Il1r2</i>	1	1.72	1.65	2.01
Interleukin 17B	<i>Il17b</i>	1	1.83	2.24	2.02
Interleukin 1 receptor, type I	<i>Il1r1</i>	1	2.10	2.04	1.77
Interleukin 6 receptor	<i>Il6ra</i>	1	2.18	2.61	1.92
* Lipopolysaccharide binding protein	<i>Lbp</i>	1	1.80	1.89	3.00
Thrombospondin 2	<i>Thbs2</i>	1	3.77	3.99	3.95
Plasminogen activator, tissue	<i>Plat</i>	1	2.06	2.37	4.25
FK506 binding protein 5	<i>Fkbp5</i>	1	6.50	6.70	8.11
Clusterin	<i>Clu</i>	1	2.71	2.71	3.20
Phosphodiesterase 10A	<i>Pde10a</i>	1	2.58	2.34	2.61
Phosphodiesterase 3A	<i>Pde3a</i>	1	2.04	2.14	2.16
Phospholipase D5 (inactive)	<i>Pld5</i>	1	11.19	12.71	8.19
Phospholipase C1	<i>Pfce1</i>	1	4.18	4.02	4.21
Phospholipase a1	<i>Plala</i>	1	2.25	2.70	3.14
Phosphodiesterase 3B	<i>Pde3b</i>	1	2.62	2.28	1.74
6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3	<i>Pfkfb3</i>	1	2.29	1.76	1.56
Phospholipase A2, group IIA	<i>Pla2g2a</i>	1	1.03	1.87	9.74
Cathepsin S	<i>Ctss</i>	1	1.05	1.27	2.86
Heat shock 22kDa protein 8	<i>Hspb8</i>	1	3.47	3.51	3.73
Heat shock protein 90kDa alpha (cytosolic), class A 1	<i>Hsp90aa1</i>	1	2.09	2.10	2.11
Heat Shock protein 105	<i>Hsph1</i>	1	3.38	3.17	3.00
Heat shock 70kDa protein 1B	<i>Hspa1b</i>	1	1.54	1.99	3.43
Tumor necrosis factor receptor superfamily, member 11b	<i>Tnfrsf11b</i>	1	1.84	1.83	2.27
Plasminogen activator, tissue	<i>Plat</i>	1	2.06	2.37	4.25
Serpin peptidase inhibitor, clade A	<i>Serpina1</i>	1	4.86	12.15	12.36
Serpin peptidase inhibitor, clade A member 3N	<i>Serpina3n</i>	1	4.79	4.37	5.05

Gene name	Gene symbol	Day 0	Day 2	Day 5	Day 15
Complement component 1, q subcomponent, C chain	<i>Clqc</i>	1	-1.34	-1.10	2.14
Chemokine (C-X-C motif) receptor 4	<i>Cxcr4</i>	1	-3.30	-3.10	-2.65
Arachidonate 15-lipoxygenase	<i>Alox15</i>	1	-2.32	-2.06	-2.81
* Prostaglandin-endoperoxide synthase 2	<i>Ptgs2</i>	1	-2.24	-2.57	-2.15
Complement component 3	<i>C3</i>	1	-3.50	-2.81	-2.05
Complement component 7	<i>C7</i>	1	-2.66	-3.69	-2.12
Neutrophilic granulocyte protein	<i>Ngp</i>	1	-7.07	-6.77	-3.86
Interferon regulatory factor 8	<i>Irf8</i>	1	-2.31	-2.78	-1.72
Defensin, alpha 1	<i>Defa1</i>	1	-7.36	-6.30	-1.81
CD93 molecule	<i>Clqr1</i>	1	-2.24	-2.65	-1.35
* Lysozyme	<i>Lyz</i>	1	-4.23	-4.31	1.19
Chemokine (C-X-C motif) receptor 2	<i>Il8rb</i>	1	-2.07	-1.76	-1.82
Chemokine (C-C motif) receptor 1	<i>Ccr1</i>	1	-2.29	-3.04	-1.79
Chemokine (C-X-C motif) ligand 12	<i>Cxcl12</i>	1	-2.35	-2.97	-1.82
Serpine Peptidase Inhibitor, Clade A	<i>Serpinh1a</i>	1	-4.62	-4.04	-2.40
Coagulation factor V (proaccelerin, labile factor)	<i>F5</i>	1	-1.86	-2.53	-1.65
* High mobility group box 2	<i>Hmgb2</i>	1	-3.83	-3.59	-3.40
S100 calcium binding protein A8	<i>S100a8</i>	1	-4.54	-4.32	-1.98
Phospholipase A2, Group VII	<i>Pla2g7</i>	1	-2.43	-3.27	-3.20
Phospholipase A2 Group IVa	<i>Pla2g4a</i>	1	-1.88	-2.06	-1.83

Footnote: Salient transcripts showing two fold or greater up- or down-regulation of DEGs following 2, 5, or 15 days of exercise as compared to unexercised controls.

* Represents genes analyzed by microarray analysis for comparison with qrtPCR dataset in Fig 1.
