Summary

While thousands of long noncoding RNAs (lncRNAs) have been identified, few lncRNAs that control neural stem cell (NSC) behavior are known. Here, we identify *Pinky* (*Pnky*) as a neural-specific lncRNA that regulates neurogenesis from NSCs in the embryonic and postnatal brain. In postnatal NSCs, *Pnky* knockdown potentiates neuronal lineage commitment and expands the transit-amplifying cell population, increasing neuron production several-fold. *Pnky* is evolutionarily conserved and expressed in NSCs of the developing human brain. In the embryonic

mouse cortex, *Pnky* knockdown increases neuronal differentiation and depletes the NSC population. *Pnky* interacts with the splicing regulator PTBP1, and PTBP1 knockdown also enhances neurogenesis. In NSCs, *Pnky* and PTBP1 regulate the expression and alternative splicing of a core set of transcripts that relates to the cellular phenotype. These data thus unveil *Pnky* as a conserved lncRNA that interacts with a key RNA processing factor and regulates neurogenesis from embryonic and postnatal NSC populations.

Introduction

Neural stem cells (NSCs) exist in both the embryonic and postnatal mammalian brain. In the embryonic cortical ventricular zone (VZ) and adult ventricular-subventricular zone (V-SVZ), NSCs are glial cells that can both self-renew and differentiate to yield intermediate progenitors that divide once or more before producing migratory young neurons (Kriegstein and Alvarez-Buylla, 2009). The production of proper numbers of neuronal progenitors from NSCs is a key aspect of brain development, and defects at this stage of the neurogenic lineage may underlie a number of human developmental disorders (Lui et al., 2011).

The mammalian genome encodes many thousands of lncRNAs – transcripts >200 nucleotides long that have no evidence of protein coding potential – and emerging data indicate that lncRNAs can have critical biological functions (Batista and Chang, 2013; Lee, 2012; Mercer and Mattick, 2013; Rinn and Chang, 2012). Although transcription factors, microRNAs, and signaling pathways that control the transition between NSCs and neurogenic progenitors have been studied intensively (Ihrie and Alvarez-Buylla, 2011; Kriegstein and Alvarez-Buylla, 2009; Lui et al., 2011), lncRNAs that regulate this critical, early stage of neurogenesis have not been identified.

Here we describe the unique developmental function of a neural-specific lncRNA we have named *Pinky* (*Pnky*) and provide insights into its molecular function. We have previously shown that knockdown of lncRNAs *Dlx1as* and *Six3os* in V-SVZ NSCs results in decreased neurogenesis (Ramos et al., 2013). Similarly, loss-of-function studies of different lncRNAs in ESC-derived NSCs (Lin et al., 2014; Ng et al., 2013), zebrafish brain (Ulitsky et al., 2011), and mouse central nervous system (Bond et al., 2009; Rapicavoli et al., 2011; Sauvageau et al., 2013) all demonstrate a loss of neuronal populations. In contrast, postnatal V-SVZ NSCs with *Pnky*-knockdown (*Pnky*-KD) generated 3-4 fold more neurons. To understand this phenotype, we used time-lapse microscopy to study lineage commitment and cell proliferation at the single-cell level. We cloned the human *PNKY* transcript and discovered its expression in the VZ of the embryonic human brain, and we demonstrated a role for *Pnky* in the development of the embryonic mouse cortex *in vivo*. Using mass spectrometry, we found that *Pnky* bound to PTBP1, an RNA-splicing factor that is a potent regulator of neural development (Keppetipola et al., 2012), direct cell reprogramming (Xue et al., 2013), and brain tumor growth (Ferrarese et al., 2014). Further analysis indicated that *Pnky* and PTBP1 modulate the expression and alternative splicing of an overlapping set of transcripts, and double-knockdown epistasis experiments suggested that *Pnky* and *Ptbp1* function in the same pathway. Overall, our work demonstrates that an evolutionarily

conserved lncRNA can regulate neurogenesis from NSCs in both the embryonic and postnatal brain.

Results

Throughout adult life, V-SVZ NSCs give rise to transit-amplifying (TA) cells, which generate neuroblasts (NB) that migrate to the olfactory bulb where they differentiate into interneurons (Doetsch et al., 1999; Lois and Alvarez-Buylla, 1994; Luskin, 1998; Peretto et al., 1997). *Pnky* (previously called *lnc-pou3f2*) is a lncRNA that we initially identified as being expressed in the adult V-SVZ (Ramos et al., 2013). RACE cloning followed by Sanger sequencing demonstrated *Pnky* to be an 825 nucleotide (nt) polyadenylated RNA encoded from three exons (**Figure 1A**). Analysis with the Coding Potential Calculator (CPC) (Kong et al., 2007), PhyloCSF (Lin et al., 2011), and the Coding-Potential Assessment Tool (CPAT) (Wang et al., 2013) indicated that the *Pnky* transcript has no protein-coding potential (**Figure S1A**). Analysis of available RNA-seq datasets indicated that *Pnky* is specifically expressed in neural tissues and lineages but is not expressed in the dentate gyrus, which contains another population of adult NSCs (**Figure 1B**). Furthermore, like many key developmental genes, the promoter of *Pnky* was “bivalent” with both histone 3 lysine 27-trimethylation (H3K27me3) and histone 3 lysine 4-trimethylation (H3K4me3) in embryonic stem cells (ESCs), coherent with its repressed but “poised” transcriptional state (**Figure 1A**). In contrast, in ESC-derived NSCs (ESC-NSCs) and V-SVZ NSCs, the *Pnky* promoter was monovalent with H3K4me3, consistent with its active transcription (**Figure 1A and S1B**).

Nuclear fractionation of V-SVZ NSC cultures followed by RT-qPCR analysis demonstrated *Pnky* to be enriched in the nucleus as compared to coding mRNAs, which were enriched in cell lysates containing cytoplasm (**Figure 1C**). Consistent with the nuclear fractionation studies, *in situ* hybridization (ISH) for *Pnky* demonstrated predominantly nuclear localization of the transcript (**Figure 1D and S1C**).

ISH of adult mouse brain tissue revealed prominent expression of *Pnky* in the V-SVZ (**Figure 1E**). To investigate whether *Pnky* expression is dynamic within the neurogenic lineage, we analyzed gene expression of V-SVZ cells acutely isolated from the brain through fluorescent activated cell sorting (FACS) (Ramos et al., 2013). Briefly, activated neural stem cells (NSCs) express both glial fibrillary acidic protein (GFAP) and the epidermal growth factor receptor (EGFR). Transit-amplifying cells are GFAP- but retain EGFR expression, and neuroblasts express cell surface marker CD24 (Pastrana et al., 2009). *Pnky* expression was highest in NSCs, and decreased by 5.6-fold ($p=0.0003$, Student's t-test) in migratory neuroblasts (**Figure 1F**). Thus, *Pnky* is normally downregulated during lineage progression *in vivo*.

To investigate the role of *Pnky* in neurogenesis, we first used V-SVZ NSC monolayer cultures that recapitulate key features of neuronal differentiation as well as glial cell production (**Figure 1G**). *Pnky* was expressed in cultured NSCs in self-renewal conditions. Upon differentiation, *Pnky* remained expressed in GFAP+ astrocytes, but was down regulated in TUJ1+ neuronal cells (**Figure S1D**), similar to the pattern of expression seen *in*

in vivo. After lentiviral transduction with control (shCtrl-GFP) or *Pnky* (sh*Pnky*-1-GFP and sh*Pnky*-2-GFP) knockdown constructs, GFP⁺ NSCs were isolated through FACS and cultured. *Pnky* knockdown was efficient in both self-renewing NSCs and after their differentiation (**Figure S1E and S1F**). Cells in these purified cultures uniformly expressed SOX2, a neural stem cell marker (**Figure S1G**). Flow cytometric analysis of these infected cells indicated that the majority (66.0%) were also positive for both GFAP and NESTIN (**Figure S1H**), markers of V-SVZ NSCs. Therefore, the majority of cells transduced with *Pnky*-KD or control vectors were GFAP⁺, NESTIN⁺, SOX2⁺ V-SVZ NSCs.

Pnky-KD NSCs incorporated the thymidine analog 5-ethynyl-2'-deoxyuridine (EdU) at the same rate as control NSCs, suggesting that proliferation in self-renewal conditions was not affected (**Figure 1H and S1I**). However, *Pnky*-KD NSCs generated 3-fold more TUJ1⁺ neuroblasts after 7 days (7d) of differentiation (**Figure 1I and 1J**). To further analyze the effect of *Pnky*-KD in the NSC population, we used a molecular-genetic method of targeting knockdown to V-SVZ NSCs (Doetsch et al., 1999; Park et al., 2014). We derived NSC cultures from G-TVA mice, which express the chicken retroviral receptor TVA from the GFAP promoter. For viral transduction of these cultures, we used shRNA lentiviruses pseudotyped with chicken viral EnvA protein, which restricts infection to the GFAP⁺ cells (**Figure S1J**). In G-TVA NSCs, *Pnky*-KD did not affect NSC proliferation in self-renewal conditions (**Figure S1K**). However, after differentiation, G-TVA NSC cultures produced a 3.56-fold more neuroblasts as compared to control (**Figure S1L**). Thus, *Pnky*-KD targeted to the GFAP⁺ NSC population in V-SVZ cultures also resulted in increased neuronal production during differentiation.

V-SVZ transit-amplifying cells express DLX2 and normally divide several times before giving rise to neuroblasts (Doetsch et al., 2002; Ponti et al., 2013). With *Pnky*-KD, there were 1.8 to 3.2 fold more EdU⁺, DLX2⁺ cells at 2d of differentiation, suggesting that *Pnky* plays a role at the transit-amplifying stage of neuronal differentiation (**Figure 1K and S1M**).

To further investigate how *Pnky*-KD increases neuronal production, we plated NSCs infected with *Pnky*-KD or control vector with large numbers of uninfected NSCs (ratio of infected GFP⁺ NSCs to uninfected NSCs was approximately 1:5000, **Fig 2A**). After 4d of differentiation, these cultures produced well-isolated clusters of GFP⁺ cells (**Figure 2B**). With *Pnky* knockdown, the proportion of GFP⁺ cell clusters containing TUJ1⁺, GFP⁺ cells was increased (**Figure 2C**). Furthermore, these clusters also contained greater numbers of TUJ1⁺, GFP⁺ neuroblasts (**Figure 2D**). These data suggested that the increased neurogenesis resulted from both a shift towards neuronal lineage commitment and an increase in cell amplification within the neurogenic lineage.

To more directly observe the clonal behavior of individual NSCs with *Pnky*-KD, we used time-lapse microscopy to image GFP⁺ cells every 15 min for 3d (**Figure 2E**). We followed the fate of 316 GFP⁺ *Pnky*-KD NSCs and 531 GFP⁺ control NSCs. After differentiation, we could identify both TUJ1⁺ neurogenic clones (**Figure S2A**) and GFAP⁺ glial clones (**Figure S2B and S2C**). Clones arising from NSCs with *Pnky*-KD were 48% more likely to

be neurogenic (**Figure 2F**). Thus, *Pnky*-KD increased the likelihood that NSCs produced neurogenic progenitors.

Neurogenic clones with *Pnky*-KD contained 2.74 fold more neuroblasts than control (**Figure S2D**). This increase in neurogenesis was in part related to an increase in progenitor cell divisions before differentiation into neuroblasts: while control progenitors divided 3.93 (SD=4.68, n=44) times and gave rise to 2.05 (SD=1.42) generations of daughter cells, *Pnky*-KD resulted in 8.94 (SD=7.64, n=33) divisions and 3.45 (SD=1.41) generations (**Figure 2G and 2H**). The average cell cycle length was not affected by *Pnky*-KD (19.4 hours vs. 19.1 hours, p=0.89) (**Figure S2E**), suggesting that the increased number of divisions related to the maintenance of a proliferative cell state and not an accelerated cell cycle. Time-lapse imaging also enabled direct observation of cell death, and the number of GFP+ neurogenic progeny (neuroblasts) that underwent cell death was reduced 57% by *Pnky*-KD (**Figure 2I**). Thus, *Pnky*-KD promoted neuronal lineage commitment from postnatal V-SVZ NSCs, increased the number of divisions of neurogenic progenitors, and reduced cell death (**Figure 2J and S2F**).

To investigate whether *Pnky* also regulates neurogenesis from other NSC populations, we next examined the embryonic brain. *Pnky* transcripts were detected in embryonic mouse brain tissue by RNA-seq (**Figure 1B**), and ISH revealed its expression in the cortical VZ – where embryonic NSCs reside – at embryonic day 14.5 (E14.5) and E16.5 (**Figure 3A, S3A, and S3B**). *Pnky* has two regions of high conservation among vertebrates (**Figure 3B and S3C**), and using strand-specific RNA-seq of gestational week 16 (GW16) human cortical samples, we detected a non-coding transcript divergent to *POU3F2* that included the conserved sequences. RACE cloning identified human *PINKY* (*PNKY*) as a polyadenylated 1592 nt transcript containing the two conserved elements and expressed from a conserved promoter region (**Figure 3B**). As in the developing mouse brain, ISH of GW14.5 human cortex demonstrated *PNKY* expression in the VZ, with decreased levels in the subventricular zone and intermediate zone (SVZ/IZ), where young neurons begin to differentiate (**Figure 3C and S3D**).

To investigate the role of *Pnky* in the mouse embryonic VZ, we electroporated *Pnky*-KD (sh*Pnky*-2-GFP) or control (shCtrl-GFP) construct into VZ cells at E13.5 (**Figure 3D**). Two days later, we analyzed GFP+ cells in the VZ, SVZ/IZ, and cortical plate (CP) (**Figure 3E**). With *Pnky* knockdown, there was a 35% decrease in the proportion of GFP+ cells in the VZ and a 26% increase in GFP+ cells in the SVZ/IZ (**Figure 3F**). We did not detect apoptotic GFP+ cells as assessed by cleaved caspase-3 staining (not shown). At this time point in cortical development, SOX2+ NSCs in the VZ produce proliferative TBR2+ progenitor cells in the SVZ/IZ that differentiate into SATB2+ young neurons. With *Pnky* knockdown, the proportion of SOX2+, GFP+ cells was reduced (**Figure 3G**). While *Pnky* knockdown did not affect the proportion of TBR2+, GFP+ TA cells or their proliferation (**Figure S3E-J**), the proportion of SATB2+, GFP+ young neurons was increased (**Figure 3H**). These data indicate that *Pnky* regulates the production of young neurons from embryonic brain NSCs *in vivo* (**Figure S3K**).

Many lncRNAs regulate gene expression through interactions with specific protein partners. To identify *Pnky*-interacting proteins, we incubated biotinylated *Pnky* (S) or antisense *Pnky* (AS) control RNA with V-SVZ NSC nuclear extract and used mass spectrometry to identify proteins that bound to the transcripts (**Figure S4A and S4B**). Polypyrimidine tract-binding protein 1 (PTBP1) was identified as a binding partner of *Pnky*, and this interaction was confirmed by Western blot analysis (**Figure 4A**). While both *Pnky* and control RNA nonspecifically bound other RNA binding proteins including HNRNPK and ELAVL1 (**Figure 4A and S4C**), only *Pnky* RNA enriched for PTBP1, suggesting that the interaction between *Pnky* and PTBP1 is specific (**Figure 4A**). Furthermore, RNA immunoprecipitation with PTBP1 antibodies enriched for *Pnky* transcript but not U1 or beta-actin mRNA (**Figure 4B**).

PTBP1 is expressed in NSCs and functions as a repressor of neuronal differentiation. In the embryonic brain, loss of *Ptbp1* results in precocious neuronal differentiation (Shibasaki et al., 2013), and in fibroblasts, *Ptbp1* knockdown leads to direct neuronal trans-differentiation (Xue et al., 2013). PTBP1 was detected in the nucleus of V-SVZ NSCs (**Figure S4D**), and *Ptbp1* knockdown resulted in larger neuronal colonies (**Figure 4C**), similar to the phenotype observed with *Pnky*-KD (**Figure 2D**).

In NSCs, PTBP1 negatively regulates the expression of *Ptbp2*, which is required for the generation of neuronal precursors (Boutz et al., 2007; Licatalosi et al., 2012). Using a PTBP2-specific antibody (Polydorides et al., 2000), we found the *Pnky* transcript did not specifically bind PTBP2 (**Figure S4E**). During neurogenesis, *Ptbp1* is normally down-regulated, and *Ptbp2* is increased (Keppetipola et al., 2012). Therefore we next characterized the relationship between *Ptbp1*, *Ptbp2*, and *Pnky* expression. Upon *Ptbp1* knockdown in V-SVZ NSCs, *Ptbp2* transcripts were upregulated, as expected (**Figure S4F**). *Ptbp1* knockdown did not decrease *Pnky* expression (**Figure S4F**). *Pnky*-KD had no effect on *Ptbp1* expression and caused a small reduction (25%) in *Ptbp2* (**Figure S4G**). Thus, the increase in neuronal differentiation observed with *Pnky*-KD does not appear to relate to changes in *Ptbp1* or *Ptbp2* expression.

PTBP1 regulates mRNA transcript levels and pre-mRNA splicing during neuronal differentiation (Keppetipola et al., 2012; Yap et al., 2012; Zheng et al., 2012). To determine whether *Pnky* and PTBP1 regulate a common set of transcripts, we performed RNA-seq of V-SVZ NSCs with either *Pnky* knockdown or *Ptbp1* knockdown. The overlap of differentially expressed genes was highly significant (**Figure 4D** and **Table S1**, 815 genes, $P = 3.8 \times 10^{-152}$) and enriched for Gene Ontology terms (Huang et al., 2009) related to cell-cell adhesion, synaptogenesis and neurogenesis (**Table S2**). Furthermore, using DEX-seq (Anders et al., 2012) to analyze differential exon usage, we found that *Pnky* knockdown and *Ptbp1* knockdown also resulted in a common set of splice variants (**Figure 4E** and **Table S3** 101 exons, $P = 1.3 \times 10^{-52}$). Thus, these data demonstrate that *Pnky* and its associated protein PTBP1 regulate an overlapping set of transcripts that underlies their role in regulating neurogenesis from V-SVZ NSCs.

To further assess whether *Pnky* and *Ptbp1* function in the same pathway, we performed an epistasis experiment. The lack of synergistic or additive effects upon combined loss of an

lncRNA and coding gene pair suggests that they function in the same molecular pathway (Dimitrova et al., 2014). Therefore, we used FACS to isolate NSCs with double knockdown of *Pnky* and *Ptbp1* as well as NSCs with each single knockdown (**Figure S4H-I**). We then analyzed the expression of several genes (*Ntsr2*, *Igfbp5*, *Scrg1*, and *Ppp1r3c*) that had been commonly upregulated by both *Pnky*-KD and PTBP1 knockdown in RNA-seq experiments (**Figure 4D**). As expected, *Ntsr2*, *Igfbp5*, *Scrg1*, and *Ppp1r3c* all had increased expression in the cells with single-knockdown as compared to control (**Figure 4F-H and S4J**). Importantly, the combined knockdown of *Pnky* and *Ptbp1* did not further enhance this gene expression (**Figure 4F-H and S4J**). These data indicate a genetic interaction between *Pnky* and *Ptbp1* and suggest that they function in the same pathway to regulate gene expression in NSCs.

Discussion

Taken together, our data indicate that *Pnky* is a conserved, neural-specific, nuclear lncRNA that interacts with PTBP1 and regulates the production of neurons from NSCs. While other lncRNAs have been found to function in central nervous system development – with lncRNA loss-of-function resulting in decreased neurogenesis (Bond et al., 2009; Chalei et al., 2014; Lin et al., 2014; Ng et al., 2013; Rapicavoli et al., 2011; Sauvageau et al., 2013; Ulitsky et al., 2011) – *Pnky* knockdown increased the production of neurons, suggesting a distinct developmental role for this lncRNA in controlling neurogenesis from NSCs. Our data are consistent with a model in which *Pnky* serves to “restrain” neuronal commitment, regulating the production of young neurons from NSCs in the developing embryonic cortex as well as those in the postnatal V-SVZ.

In the developing cortex, we found that *Pnky*-KD resulted in an increase in young neurons and decreased the NSC population in the VZ. This did not appear to involve a change in the proliferation of the transit amplifying cells of this embryonic lineage. In V-SVZ NSCs from the postnatal brain, *Pnky*-KD also promoted neuronal differentiation, and we additionally observed greater numbers of divisions of the neurogenic progenitor cells. Thus, the phenotypes of *Pnky*-KD in these two very different NSC populations are largely similar in that neuronal differentiation is increased. Interestingly, *Pnky* does not appear to regulate all NSC populations, as we did not detect *Pnky* transcripts in the dentate gyrus, which harbors another population adult NSCs.

Our studies indicated that *Pnky* interacts with PTBP1, which is a key regulator of neural development (Shibasaki et al., 2013). PTBP1 is also a powerful mediator of cell reprogramming (Xue et al., 2013), and its depletion from fibroblasts can lead to direct trans-differentiation into neurons. Moreover, PTBP1 is a potent driver of brain tumor growth and invasiveness (Ferrarese et al., 2014). During neuronal differentiation, PTBP1 is normally downregulated, and there is an increase in PTPB2. We did not find evidence for a specific interaction between *Pnky* and PTPB2 or other nuclear RNA-binding proteins such as HNRNPK and ELAVL1. These data suggest that *Pnky* and PTPB1 – a splicing factor with critical functions in both normal development and brain tumors – are part of a specific ribonucleoprotein complex in NSCs.

Given this physical interaction between *Pnky* and PTBP1, we worked towards understanding whether this lncRNA and protein partner function together. First, we found that both *Pnky* and PTPB1 knockdown in V-SVZ NSCs promoted neurogenesis. Furthermore, *Pnky*-KD promoted neuronal differentiation in the developing cortex, and mice with *Ptbp1* loss-of-function also exhibit precocious cortical neurogenesis. Thus, *Pnky*-KD and loss of PTBP1 produce similar phenotypic results. Second, we found that *Pnky*-KD and PTBP1-knockdown produced gene expression changes as well as splicing changes that were highly similar, indicating that *Pnky* and PTPB1 regulate a common set of transcripts related to neuronal differentiation. Third, our epistasis experiment indicated that *Pnky* and PTBP1 double knockdown does not produce changes greater than single knockdowns. Thus, the physical interaction between *Pnky* and PTBP1 along with the evidence for their genetic interaction is consistent with a model in which they function together in a common molecular pathway. Whether the physical interaction between *Pnky* and PTPB1 is required for their regulation of neuronal differentiation remains to be tested directly. Future work may reveal an interplay between lncRNAs and PTBP1 in different biological contexts, including cancer and direct cell reprogramming.

Experimental Procedures

V-SVZ NSC cultures

Postnatal day 5-7 (P5-7) C57/B6 mouse brains were used to derive V-SVZ cultures as in (Park et al., 2014). Cells were split 1:2 to passage 5 or 6 before switching from self-renewal to differentiation medium as described (Park et al., 2014).

In situ hybridization

Branched DNA *in situ* was performed on adult tissue with the RNAScope 2.0 high definition BROWN kit (ACD). *In situ*s on embryonic tissue were performed as described (Wallace and Raff, 1999) with DIG-labeled RNA probes.

Time-lapse imaging

Cultures were established by trypsinization and subsequent mixing of infected cultures (shCtrl or sh*Pnky*) with wildtype cells at a ratio of 1:200 to give ~15 GFP+ cells/high power field. Cultures were switched to differentiation medium and imaged on a Leica SP5 inverted confocal microscope fitted with a Life Imaging Services microscope temperature control system. 8 optical sections were taken every 15 minutes for 3 days. Cell fate was determined by morphology, and representative fields were analyzed by ICC for Tuj1 and GFAP.

Human Fetal Tissue

Fetal cortical tissue was collected from elective pregnancy termination specimens at San Francisco General Hospital, usually within 2h of the procedure. Research protocols were approved by the UCSF Committee on Human Research.

***In utero* electroporation**

In utero electroporation was performed on E13.5 embryos from timed-pregnant wildtype Swiss-Webster mice (Simonsen labs) as described (Saito, 2006). Constructs used were PsicoR-shLuciferase (shCtrl), and PsicoR-sh*Pnky-2* (sh*Pnky*). Embryos were harvested 48 hours later. 1-3 non-adjacent coronal sections per brain were imaged for quantification. Four animals from three separate surgeries were quantified for each experiment.

RNA-pulldown and Mass Spectrometry

Biotinylated RNA pulldown was performed as in (Hacisuleyman et al., 2014). Selected SDS PAGE-separated bands were excised and in-gel digested with trypsin as in (Jiménez et al., 2001). LC-MS analyses of tryptic peptides utilized LTQ Orbitrap Velos mass spectrometer (Thermo Scientific) equipped with a NanoLC Ultra System (Eksigent), as described (Roan et al., 2014).

RNA-seq analysis

Cluster generation and high-throughput sequencing were performed on a HiSeq 2500 (Illumina), using the paired-end 100 bp protocol. Reads were aligned to the mouse genome mm9 using Tophat v2.0.10 (Trapnell et al., 2009). Differential expression was assessed using Cuffdiff v2.1.1 (Trapnell et al., 2010). Alternative splicing was analyzed using DEXSeq v1.8.0 (Anders et al., 2012), using an FDR threshold of 0.01. Data are deposited in NCBI GEO under accession number GSE65542.

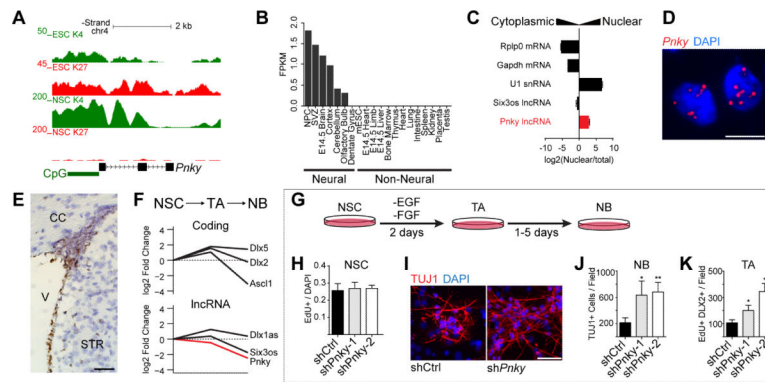

Figure 1. The lncRNA *Pinky* is expressed in SVZ-NSCs and regulates neuronal differentiation

A) UCSC genome browser view of the *Pinky* locus. Also shown are ChIP-seq tracks for H3K4me3 and H3K27me3 in ESCs and V-SVZ NSCs. B) Fragments per kilobase per million mapped reads (FPKM) values for *Pinky* in indicated tissues. C) Subcellular fractionation followed by RT-qPCR for indicated lncRNAs and mRNAs. Error bars are propagated standard deviation (S.D.) from technical triplicate wells. D) Branched-DNA ISH for *Pinky* in V-SVZ NSC cultures. Nuclei are counter-stained with 4',6-diamidino-2-phenylindole (DAPI). Scale bar = 10 μ m. E) Branched-DNA ISH for *Pinky* (brown) in adult mouse coronal brain section. Nuclei are counter-stained with hematoxylin. V = ventricle, CC = corpus collosum, STR = striatum. Scale bar = 50 μ m. F) Microarray expression analysis from FACS-isolated neural stem cells (NSC), transit-amplifying cells (TA), and neuroblasts (NB). Value in NSCs set to 0. G) Schematic of V-SVZ NSC culture system. H) Quantification of EdU labeling counted from GFP+ cultures of V-SVZ NSCs infected with control or *Pinky*-KD constructs. I) ICC for TUJ1 (red) after 7d of differentiation in control or *Pinky*-KD GFP+ cultures. Nuclei are counter-stained with DAPI (blue). Scale bar = 50 μ m. J) Quantification of TUJ1+ NBs produced after 7d differentiation. K) Quantification of the number of TA cells after 2d of differentiation. Error bars for H, J, and K are S.D. from triplicate wells, * $p < 0.05$, ** $p < 0.01$, Student's t-test. See also Figure S1.

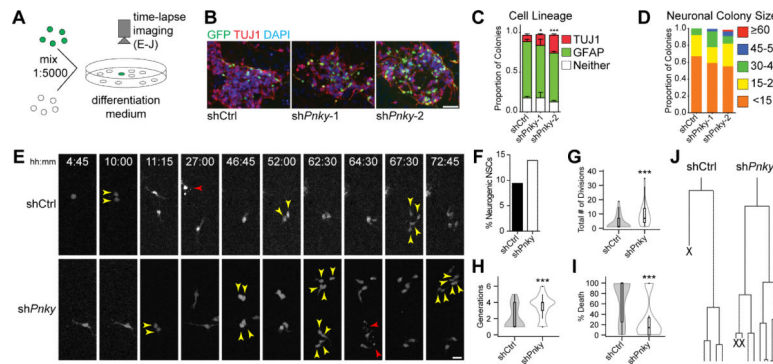

Figure 2. *Pinky* knockdown leads to an expansion of neurogenic transit-amplifying progenitors
 A) Schematic of experimental design. B) Representative images of isolated colonies after 4d of differentiation. ICC for TUJ1 (red) and GFP (green). Nuclei are DAPI counterstained (blue). Scale bar = 50 μ m. C) Quantification of the fate of isolated GFP+ colonies. Error bars = S.D. of triplicate experiments. D) Quantification of TUJ1+ neuroblasts found in individual neurogenic colonies. E) Representative frames from time-lapse video of control (top) or *Pnky*-KD (bottom) single cells. Time of differentiation is indicated. Yellow arrows indicate daughter cells resulting from a recent division, red arrows indicate cell death. Scale bar = 25 μ m. F) Bar graph representing the percentage of initial tracked progenitors that gave rise to neuroblasts. N= 531 GFP+ shCtrl NSCs and 316 GFP+ sh*Pnky* NSCs. G) Violin plots overlaying box-and-whisker plots of total number of divisions undergone by a single initial neurogenic progenitor and all of its daughter cells. N = 44 shCtrl and 33 sh*Pnky* progenitors. H) Violin plots overlaying box-and-whisker plots of the number of generations per initial neurogenic progenitor for shCtrl and sh*Pnky*. N = 44 shCtrl and 33 sh*Pnky* progenitors. I) Violin plots overlaying box-and-whisker plots of % of progeny per single neurogenic progenitor that underwent cell death. N = 44 shCtrl and 33 sh*Pnky* progenitors. J) Tree diagram for the frames shown in E and corresponding time-lapse movies. X indicates cell underwent cell death. * $p < 0.05$ *** $p < 0.001$, Student's t-test. See also Figure S2.

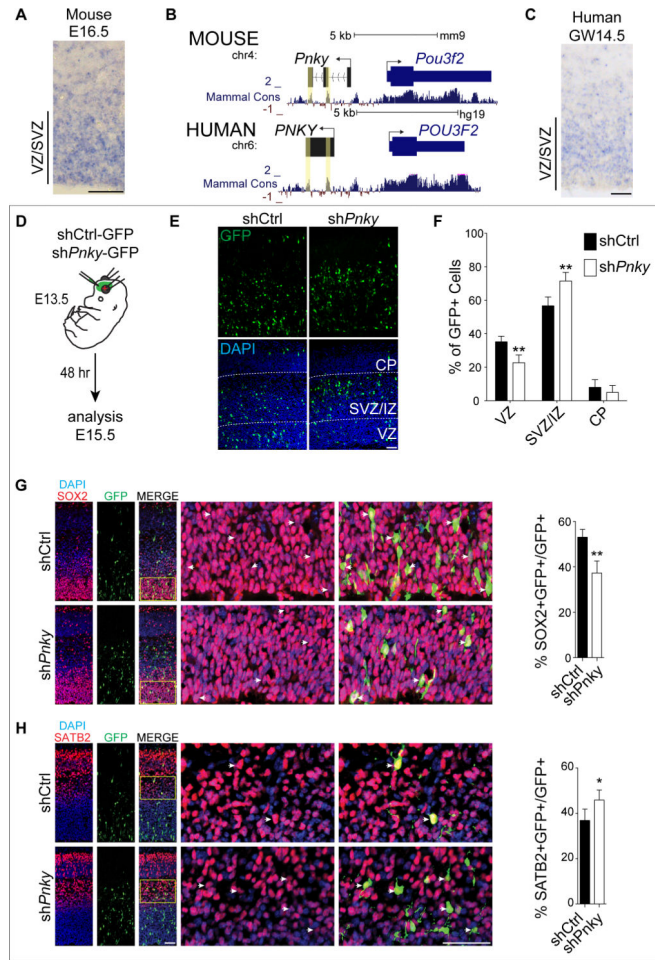

Figure 3. *Pinky* is expressed in the developing mouse and human cortex and regulates the differentiation of mouse cortical progenitors *in vivo*

A) ISH for *Pnky* in embryonic day 16.5 (E16.5) mouse brain. B) Genome browser track showing two regions of high conservation, determined by PhyloP score (yellow boxes). Human *PNKY* genomic region is shown below with conservation indicated. For clarity, the mouse – strand is shown left to right. C) ISH for *PNKY* in gestational week 14.5 (GW14.5) human brain. D) Schematic of *in utero* electroporation of mouse embryonic brain. E) Cortical sections at E15.5, 2d after electroporation with shCtrl (left) or sh*Pnky* (right). IHC for GFP (top) and with DAPI counterstain (bottom). VZ = ventricular zone, SVZ/IZ = subventricular zone/intermediate zone, CP = cortical plate. F) Quantification of GFP+ cell distribution in indicated zones as a percentage of total GFP+ cells. G) Left: Cortical sections at E15.5, 2d after electroporation with shCtrl or sh*Pnky*. IHC for GFP (green) and SOX2 (red), with DAPI nuclear counterstain (blue). Yellow box indicates region enlarged in the adjacent panels. Arrowheads indicate co-labeled cells. Right: quantification of SOX2+, GFP+ cells as a percentage of total GFP+ cells. H) Left: Cortical sections immunostained for GFP (green) and SATB2 (red), with DAPI nuclear counterstain (blue). Yellow box indicates region enlarged in the adjacent panels. Right: Quantification of SATB2+, GFP+ cells as a percentage of total GFP+ cells. All error bars are S.D., n=4 brains of each condition from 3 separate surgeries. *p<0.05, **p<0.01. All scale bars = 50 μm. See also Figure S3.

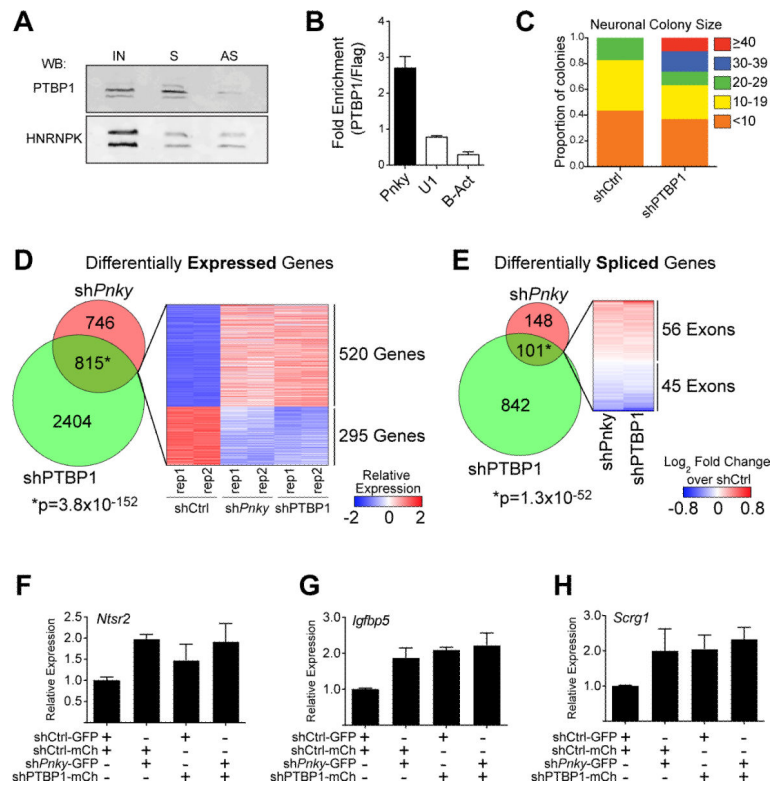

Figure 4. *Pinky* interacts with PTBP1 and regulates transcript expression and differential splicing

A) Immunoblot for PTBP1 or HNRNPK following RNA-pulldown with biotin-labeled sense (S) or anti-sense (AS) *Pnky* RNA incubated with V-SVZ NSC nuclear extract. IN = input V-SVZ nuclear extract. B) RT-qPCR detection for indicated RNA recovered by PTBP1-specific antibody normalized to control FLAG antibody. Error bars are propagated S.D. from technical triplicates. C) Quantification of number of TUJ1+ neuroblasts found in individual neurogenic colonies with *Ptbp1*-knockdown or control. D) Venn Diagram demonstrating the overlap between genes differentially expressed (FDR < 0.05) upon *Ptbp1* or *Pnky* knockdown. Heatmap representation of the differential expression of the overlapping gene set in shCtrl, sh*Pnky*, and sh*Ptbp1* biological duplicate cultures. E) Venn Diagram demonstrating the overlap between exons showing differential usage (FDR < 0.01) upon *Ptbp1* or *Pnky* knockdown. Heatmap representation of the differential usage of the overlapping gene set in sh*Pnky* and sh*Ptbp1* cultures compared to control. F-H) RT-qPCR detection of expression of indicated genes normalized to *Gapdh*. Expression in each condition is shown relative to control (shCtrl-GFP, shCtrl-mCherry). Error bars are 95% confidence intervals from 3 separate cultures. See also Figure S4 and Tables S1-S3.
