Abstract

Just as we intuitively know that "chair" and "boy" denote referents in different categories, we know that "standing" falls into a different category from "walking": One of the events is static, the other dynamic. In three self-paced reading experiments, we show that such differences in event dynamicity leads to expectations about the temporal structure of complex events. We replicate and extend Gennari (2004): Participants read complement (Exp.1) and relative clause constructions (Exp.2,3) in which the event type in the subordinate clause (i.e., event/state) and temporal proximity between main and subordinate clause situations (i.e., close/overlap vs. distant/non-overlap) were manipulated. Consistent with Gennari (2004), we find evidence that people expect states to overlap (Exp.1,2), but only when in line with their expectation that states should happen first in time (Exp.3). Our results support a multifactorial model of language comprehension in which event structure is central to the formation of temporal expectations.
