-1-

The Hyperfine Coupling Constants and Rates  
of Exchange for  $C^{13}N^-$  with the Axial  
and Equatorial Positions in  $Cr(CN)_5NO^{-3}$

J. Brock Spencer and Rollie J. Myers

January 1964

It has been recently reported<sup>1,2</sup> that the magnetic hyperfine interaction of  $C^{13}$  was observable in paramagnetic resonance spectrum of aqueous solutions of  $Cr(CN)_5NO^{-3}$ . It seemed probable that this interaction was only due to the equatorial  $CN^-$  but the possible axial coupling remained unknown. In a preliminary report<sup>3</sup> of the exchange with  $C^{13}N^-$  we were also unable to differentiate between the axial and equatorial positions. We have now been able to prepare the complex by exchange with  $C^{13}$  substituted primarily in the axial position and by synthesis with every cyanide substituted by  $C^{13}N^-$ . Both the hyperfine interaction and the rates of exchange of the axial and equatorial positions have now been clearly resolved.

Samples of  $K_3Cr(CN)_5NO$  were synthesized<sup>4</sup> utilizing NaCN enriched to 55% in  $C^{13}$  isotope. The largest hyperfine splitting in the paramagnetic resonance spectrum of  $Cr(CN)_5NO^{-3}$  should arise from the species containing<sup>5</sup>  $Cr^{53}$ ,  $N^{14}$  and five  $C^{13}$ . In the X-band spectrum of the enriched sample clearly resolved lines occur 62.4 gauss above and below the center of the spectrum. Since these lines must be due to a combination of axial and equatorial  $C^{13}$

hyperfine interaction, this splitting can be combined with the previously assigned<sup>1,2</sup>  $C^{53}$ ,  $N^{14}$  and  $C^{13}$  equatorial splittings to yield a value of  $8.55 \pm 0.4$  gauss for the axial  $C^{13}$  coupling constant.

A prominent hyperfine line can also be observed between the  $C^{12}$  and the expected equatorial  $C^{13}$  lines when the complex is exchanged in solutions containing nearly equal amounts of  $C^{13}$  enriched  $CN^-$  and HCN. Direct measurement of this line gives  $8.93 \pm 0.2$  gauss for the axial  $C^{13}$  coupling constant. Our values can be compared to the  $8.43 \pm 0.2$  gauss reported by Kuska and Rogers<sup>6</sup> from a resolution of the complex pattern observed for both axial and equatorial  $C^{13}$  substitution. A summary of our coupling constants is given in Table I.

In the temperature range 60-100°C the exchange with  $C^{13}N^-$  can be observed without decomposition of the complex. We have followed the decrease in the signal due to unsubstituted complex and the increase in the signal resulting from equatorial  $C^{13}$  substitution while the samples were held at constant temperature in the microwave cavity of a paramagnetic resonance spectrometer. In solutions ranging from 0.015 - 0.035 f in complex and 0.1-0.2 f in NaCN (55% in  $C^{13}$  isotope) we followed the adjacent lines for unsubstituted and  $C^{13}$  equatorial-substituted complex for the  $Cr^{53}$  species until approximately 50% of the complex was substituted with one  $C^{13}N^-$ . These experiments were conducted in the nearly complete darkness of the cavity. In separate experiments no pronounced light catalysis, as reported for other cyanide complexes,<sup>7</sup> was observed.

These exchange data were fit by rate laws assuming first order in unsubstituted complex and zero order in total  $CN^-$  concentration. An integrated rate law was used which took into account the possible substitution

of the axial and one of the four possible equatorial  $\text{CN}^-$ . The total rate constant  $k_a + 4k_e$  can be directly obtained from the decrease in the unsubstituted complex and the equatorial rate constant  $k_e$  can be evaluated by successive approximation from the growth of the equatorial  $\text{C}^{13}$  signal. At  $75^\circ\text{C}$  we obtain  $k_a = 1 \times 10^{-4} \text{ sec}^{-1}$  and  $k_e = 7 \times 10^{-6} \text{ sec}^{-1}$ . Over the range of temperatures we get  $\Delta H_a^\ddagger = 33.5 \pm 4 \text{ Kcal/mole}$ ,  $\Delta S_a^\ddagger = 18 \pm 8 \text{ e.u.}$ ,  $\Delta H_e^\ddagger = 30.5 \pm 4 \text{ Kcal/mole}$  and  $\Delta S_e^\ddagger = 5 \pm 8 \text{ e.u.}$  In the solutions prepared by adding  $\text{NaCN}$  to neutral solutions of the complex the ratio  $k_a/4k_e = 4 \pm 2$  over the full range of temperature.

The apparent large positive value for  $\Delta S_a^\ddagger$  indicates<sup>8</sup> that the activated complex for axial exchange is a protonated species. The formation of  $\text{HCr}(\text{CN})_5\text{NO}^{-2}$  by the removal of the proton from  $\text{HCN}$  could contribute about 40 e.u. to the apparent entropy of activation. When exchange experiments were conducted in acidified solutions so that both  $\text{CN}^-$  and  $\text{HCN}$  have nearly equal concentrations the axial rate is accelerated. In this case, as previously mentioned, a line due to axial substitution becomes prominent before the equatorial line is clearly observable. It seems probable that the formal charge of +1 on the  $\text{NO}$  group makes the axial  $\text{CN}^-$  more likely for protonation than the more adjacent equatorial  $\text{CN}^-$ . It is possible from our data, however, that the equatorial exchange is also partly acid catalyzed.

The similar values for the  $\text{N}^{14}$  and both  $\text{C}^{13}$  coupling constants do not give any clear contradiction or support to the bonding scheme proposed<sup>9</sup> for these complexes. The axial  $\text{CN}^-$  is more liable to exchange in aqueous solution primarily because of greater protonation at this position, and the enthalpies of activation are equally large for both positions. The theory for the isotropic hyperfine interaction in these compounds is necessarily complex, and both the signs of the coupling constants and the anisotropic terms

should be determined before a serious effort is made to explain the axial and equatorial coupling constants in terms of bonding.

Acknowledgment- This work was supported by a grant from the United States Atomic Energy Commission.

Table I  
Hyperfine Coupling Constants

$A(\text{Cr}^{53})$	$18.39 \pm 0.05$ gauss
$A(\text{N}^{14})$	$5.27 \pm 0.05$
$A(\text{C}_e^{13})$	$12.64 \pm 0.2$
$A(\text{C}_a^{13})$	$8.80 \pm 0.3$
