(Received 29 August 2000; published 11 January 2001)

We have synthesized the series of compounds  $R\text{MIn}_5$  and  $R_2M\text{In}_8$  in single crystal form, where  $R=\text{Sm}$  or  $\text{Gd}$  and  $M=\text{Rh}$  or  $\text{Ir}$ . These materials form in tetragonal derivatives of the  $\text{Cu}_3\text{Au}$  structure  $R\text{In}_3$ . Measurements of magnetic susceptibility, electrical resistivity, and low-temperature heat capacity are reported. These compounds order antiferromagnetically at low temperature ( $T_N < 45$  K) and their low-temperature magnetic properties remain nearly unaltered compared to their  $\text{SmIn}_3$  and  $\text{GdIn}_3$  cubic relatives. The present data are compared to the magnetic properties of the isostructural  $(\text{Ce},\text{Nd})(\text{Rh},\text{Ir})\text{In}_5$  and  $(\text{Ce},\text{Nd})_2(\text{Rh},\text{Ir})\text{In}_8$  compounds, and the validity of de Gennes scaling as a function of rare earth in a given structure is discussed.

## I. INTRODUCTION

Recently, a new series of  $R_mM\text{In}_{3m+2}$  tetragonal variants of the  $\text{Cu}_3\text{Au}$ -structure compounds for  $M=\text{Rh}$  or  $\text{Ir}$ ,  $m=1,2$ ; and  $R=\text{light rare earth}$  have become a particularly relevant area of research since the discovery of a new class of heavy-fermion superconductors for some of the Ce-based compounds.<sup>1-3</sup> The  $R_mM\text{In}_{3m+2}$  tetragonal structures can be viewed as  $m$  layers of  $R\text{In}_3$  units stacked sequentially along the  $c$  axis with intervening layers of  $M\text{In}_2$  (Ref. 4) and unconventional magnetic and superconducting behavior have been reported for  $\text{CeRhIn}_5$  (Ref. 1) and  $\text{CeIrIn}_5$ .<sup>2</sup> The first one is an antiferromagnet at ambient pressure ( $T_N \approx 3.8$  K and  $\gamma \approx 400$  mJ/mol K<sup>2</sup>),<sup>1</sup> and presents an unconventional evolution to a superconducting state for  $P > P_c \approx 16$  kbars where superconductivity sets in at  $T_c \approx 2$  K.  $\text{CeIrIn}_5$  shows ambient-pressure heavy-fermion superconductivity at  $T_c \approx 0.4$  K with a Sommerfeld coefficient of  $\gamma \approx 720$  mJ/mol K<sup>2</sup>.<sup>2</sup> The  $m=2$  variants of these Ce-based compounds include an antiferromagnetic ground state ( $T_N \approx 2.8$  K and  $\gamma \approx 400$  mJ/mol K<sup>2</sup>) for  $\text{Ce}_2\text{RhIn}_8$ , while  $\text{Ce}_2\text{IrIn}_8$  remains a heavy-fermion paramagnet to 50 mK, with no evidence for a phase transition ( $\gamma \approx 700$  mJ/mol K<sup>2</sup>).<sup>3</sup>

It has been suggested that the reduced spatial dimensionality and magnetic anisotropy resulting from the quasi-two-dimensional structure of these compounds may control the nature of their heavy-fermion ground states.<sup>1,3</sup> Furthermore, studies of  $\text{Nd}M\text{In}_5$  and  $\text{Nd}_2M\text{In}_8$  analogs for  $M=\text{Rh}$  or  $\text{Ir}$  suggest that crystal-field effects (CEF's) and related magnetic anisotropy play an important role in the evolution of the magnetic properties within these series.<sup>5</sup> Therefore studies of the magnetic properties through the rare earths for  $R_mM_n\text{In}_{3m+2n}$  ( $M=\text{Rh}$  or  $\text{Ir}$ ) appear to be a promising investigation. The Pr-based homologues are nonmagnetic singlet ground-state systems and a detailed CEF analysis of these materials will be given elsewhere.<sup>6</sup>

In the present work, we report magnetic susceptibility, electrical resistivity, and heat-capacity measurements on  $(\text{Gd},\text{Sm})M\text{In}_5$  and  $(\text{Gd},\text{Sm})_2M\text{In}_8$  single crystals, for  $M=\text{Rh}$  or  $\text{Ir}$ . Each orders antiferromagnetically with  $T_N \lesssim 45$  K. Comparisons to their cubic relative  $(\text{Gd},\text{Sm})\text{In}_3$  suggest

that the insertion of  $M\text{In}_2$  layers along the  $c$  axis in  $(\text{Gd},\text{Sm})M\text{In}_5$  and  $(\text{Gd},\text{Sm})_2M\text{In}_8$  ( $M=\text{Rh}$  or  $\text{Ir}$ ) only weakly affects the low-temperature magnetic ground state for the tetragonal variants. The data for the Ce and Nd-based homologues are also included to help the discussion.

## II. EXPERIMENT

Single crystalline samples of the  $(\text{Gd},\text{Sm})M\text{In}_5$  and  $(\text{Gd},\text{Sm})_2M\text{In}_8$  ( $M=\text{Rh}$  or  $\text{Ir}$ ) compounds were grown from the melt in In flux as described previously.<sup>1</sup> Typical crystal sizes were  $1 \times 1$  cm  $\times$  several mm. The tetragonal  $\text{HoCoGa}_5$  ( $m=1$ ) (Ref. 4) and  $\text{Ho}_2\text{CoGa}_8$  ( $m=2$ ) (Ref. 7) structure types and phase purity were confirmed by x-ray powder diffraction, and the crystal orientation was determined by the usual Laue method. The lattice parameters  $a$  and  $c$  for the studied compounds are given in Table I. Lattice constants for the nonmagnetic variants  $\text{La}M\text{In}_5$  and  $\text{La}_2M\text{In}_8$  are also included for reference. Specific-heat measurements were per-

FIG. 1. Temperature dependence of the magnetic susceptibility, for applied field  $H$  along the  $c$  axis,  $\chi_{||}$  (open symbols), and in the  $ab$  plane,  $\chi_{\perp}$  (solid symbols), for  $Gd_mMIn_{3m+2}$  ( $M=Rh$  or  $Ir$ ) materials (a) for  $m=1$  and (b) for  $m=2$ . The  $\mu_{eff}$  and  $\theta_p$ , obtained from Curie-Weiss law fitting for  $T > 150$  K are given in Table I.

formed in a small-mass calorimeter that employs a quasi-adiabatic thermal relaxation technique.<sup>8</sup> Samples used here ranged from 10 to 30 mg. Magnetization measurements were made in a Quantum Design dc superconducting quantum interference device and electrical resistivity was measured using a low-frequency ac resistance bridge and four-contact configuration.

### III. RESULTS

Figures 1 and 2 present the temperature dependence of the magnetic susceptibility, for an applied field  $H$  along the  $c$  axis,  $\chi_{||}$ , and in the  $ab$  plane,  $\chi_{\perp}$ , for the  $Gd_mMIn_{3m+2}$  and  $Sm_mMIn_{3m+2}$  materials, respectively. Each shows antiferromagnetic order, with  $T_N < 45$  K. For the Gd-based materials the magnetic susceptibility is significantly anisotropic only below  $T_N$  showing a typical anisotropy of an antiferromagnet with an easy axis in the plane. The effective magnetic mo-

FIG. 2. Temperature dependence of the magnetic susceptibility, for applied field  $H$  along the  $c$  axis,  $\chi_{||}$  (open symbols), and in the  $ab$  plane,  $\chi_{\perp}$  (solid symbols), for  $Sm_mMIn_{3m+2}$  ( $M=Rh$  or  $Ir$ ) materials (a) for  $m=1$  and (b) for  $m=2$ .

FIG. 3. Temperature dependence of the electrical resistivity for  $(Gd,Sm)MIn_5$  and  $(Gd,Sm)_2MIn_8$  ( $M=Rh$  or  $Ir$ ) single crystals. The solid arrows point out the Néel temperatures for the compounds while the dashed arrows mark possible extra features below  $T_N$ .

ment ( $\mu_{eff}$ ) and the paramagnetic Curie-Weiss temperatures ( $\theta_p$ ) obtained from Curie-Weiss law fits for  $T > 150$  K for the Gd-based compounds are given in Table I. In the Sm-based case, the high-temperature magnetic anisotropy is probably associated with CEF in both ground  $J=5/2$  and excited  $J=7/2$  multiplet states of the  $Sm^{3+}$  ion.<sup>9,10</sup> As typical in Sm-based materials, the high- $T$  behavior of the inverse of magnetic susceptibility does not show a linear temperature dependence due to a Van Vleck contribution (which complicates the extraction of  $\mu_{eff}$  and  $\theta_p$  from the data).<sup>9,10</sup>

The temperature dependence of the electrical resistivity for  $(Gd,Sm)MIn_5$  and  $(Gd,Sm)_2MIn_8$  ( $M=Rh$  or  $Ir$ ) single crystals is plotted in Fig. 3. The room-temperature value of the electrical resistivity varies between 20 and 30  $\mu\Omega$  cm and the high-temperature data show a metallic behavior for these compounds. At low temperatures, clear features can be seen at the respective ordering temperatures for all compounds. For the Sm-based homologues extra features also may be present in the data for  $T < T_N$  for some of the compounds.

Figure 4 shows the specific heat divided by temperature (a) and the corresponding magnetic entropy (b) in the temperature range  $2 \lesssim T \lesssim 20$  K, for  $SmMIn_5$  and  $Sm_2MIn_8$  ( $M=Rh$  or  $Ir$ ).

To calculate the magnetic entropy, the phonon contribution was estimated from the specific-heat data of  $LaMIn_5$  (Refs. 1 and 2) and  $La_2MIn_8$  (Ref. 3) ( $M=Rh$  or  $Ir$ ) and subtracted from the total specific heat of the magnetic compounds. The main peaks in  $C/T$  corresponding to the onset of antiferromagnetic order can be seen at  $T_N=14.18$  and 14.30 K for  $Sm_2IrIn_8$  and  $SmIrIn_5$ , respectively, and at 15.00 K for both  $SmRhIn_5$  and  $Sm_2RhIn_8$  [Fig. 4(a)].

The Néel temperatures obtained from the specific-heat data are in very good agreement with the temperatures where the maximum in the magnetic susceptibility occurs (see Fig. 2).

For the  $Sm_2IrIn_8$ , the antiferromagnetic transition at 14.18 K was found to be a first order transition with a latent heat of  $\sim 10$  J/mol. However, no hysteresis was observed in the re-

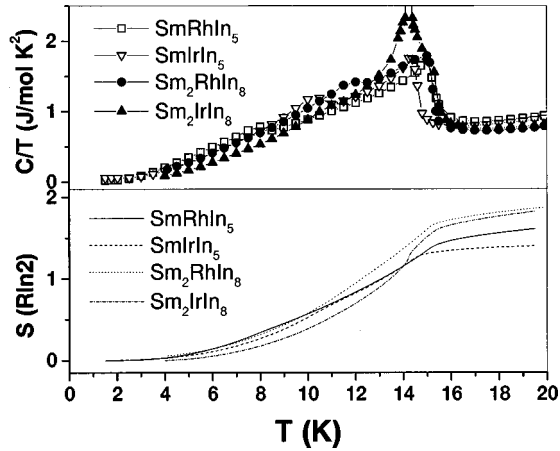

FIG. 4. Specific-heat data divided by temperature (a) and the corresponding magnetic entropy (b) in the temperature range  $2 \lesssim T \lesssim 20$  K for  $\text{Sm}M\text{In}_5$  and  $\text{Sm}_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ).

sistivity or magnetic susceptibility measurements as a function of temperature. The magnetic entropy recovered by  $T_N$  ranges between  $1.4$  and  $1.8R \ln 2$  [Fig. 4(b)], suggesting that the magnetic order develops in a crystal-field doublet ground state with a nearby doublet excited state. Below  $T_N$ , a secondary feature in  $C_m/T$  was observed at  $11.5$ ,  $10.0$ ,  $8.0$ , and  $12.0$  K for  $\text{Sm}_2\text{IrIn}_8$ ,  $\text{SmIrIn}_5$ ,  $\text{SmRhIn}_5$ , and  $\text{Sm}_2\text{RhIn}_8$ , respectively [Fig. 4(a)]. These secondary peaks are coincident with features in the resistivity for some of the compounds (see Fig. 3). Similar extra transitions below  $T_N$  also have been reported for  $\text{SmIn}_3$  and they have been interpreted as successive magnetic transitions associated with quadrupolar ordering.<sup>11</sup>

#### IV. DISCUSSION

The cubic compounds  $R\text{In}_3$  are antiferromagnets with  $T_N \lesssim 50$  K (Ref. 9) and their  $T_N$  and  $\theta_p$  values follow de Gennes scaling quite well, with the exception of  $\text{CeIn}_3$ ,<sup>9</sup>  $\text{NdIn}_3$  and  $\text{SmIn}_3$ , whose magnetic order develops in a  $\Gamma_8$  quartet crystal-field ground state, present additional magnetic transitions below  $T_N$ .<sup>11–13</sup> These complex magnetic states with successive magnet ordering arise due to the presence of magnetoelastic effects and both bilinear and quadrupolar exchange interactions.<sup>11–13</sup>

Surprisingly, the insertion of  $m M\text{In}_2$  layers along the  $c$  axis in  $(\text{Gd}, \text{Sm})M\text{In}_5$  and  $(\text{Gd}, \text{Sm})_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ) causes no significant changes in their Néel temperatures, whereas  $T_N$  shows a strong variation among the Ce- and Nd-based homologous.<sup>3,5</sup> It has been reported that the magnetization easy axis for  $(\text{Ce}, \text{Nd})M\text{In}_5$  and  $(\text{Ce}, \text{Nd})_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ) is along the  $c$  axis,<sup>3,5</sup> while the present data (see Figs. 1 and 2) suggest an easy axis in the  $ab$  plane for the  $(\text{Gd}, \text{Sm})M\text{In}_5$  and  $(\text{Gd}, \text{Sm})_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ) compounds. As we discuss below, this change in the direction of the magnetic easy axis may be related to a reduction through the rare earths in the competing anisotropic magnetocrystalline and crystal-field effects reported for Ce and Nd.<sup>3,5</sup>

In order to discuss the evolution of the magnetic properties of the  $RM\text{In}_5$  and  $R_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ), we plot the

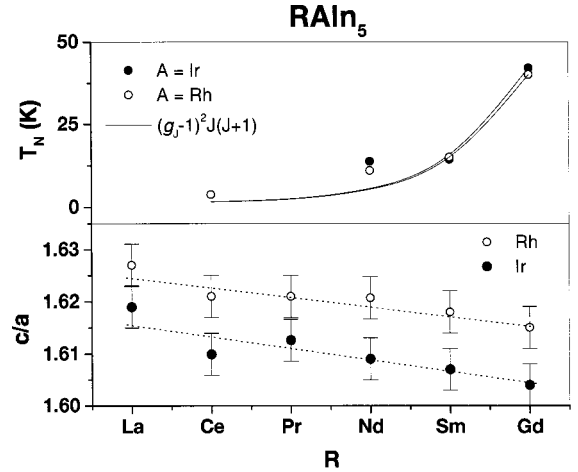

FIG. 5.  $T_N$  and  $c/a$  values plotted through the rare-earth series for the  $RM\text{In}_5$  ( $M = \text{Rh}$  or  $\text{Ir}$ ) compounds. The solid lines are the de Gennes factor  $[(g_J^2 - 1)^2 J(J+1)]$  for ground-state multiplet  $J$  of the rare earths normalized by the  $\text{Gd}M\text{In}_5$  ( $M = \text{Rh}$  or  $\text{Ir}$ )  $T_N$  values and the dashed lines are a guide for the eye.

$T_N$  and  $c/a$  ratio (see also Table I) for  $RM\text{In}_5$  ( $R = \text{Ce}, \text{Nd}, \text{Sm}, \text{Gd}$ ;  $M = \text{Rh}, \text{Ir}$ ) and  $R_2M\text{In}_8$  ( $R = \text{Ce}, \text{Nd}, \text{Sm}, \text{Gd}$ ;  $M = \text{Rh}$  or  $\text{Ir}$ ) in Figs. 5 and 6, respectively. Figure 7 shows the evolution of the Néel temperature for the homologous  $RM\text{In}_5$  and  $R_2M\text{In}_8$  ( $R = \text{Ce}, \text{Nd}, \text{Gd}, \text{Sm}$ ;  $M = \text{Rh}$  or  $\text{Ir}$ ) compounds compared to their cubic  $R\text{In}_3$  ( $\text{Ce}, \text{Nd}, \text{Sm}, \text{Gd}$ ) relatives.

The solid lines in Figs. 5 and 6 are the de Gennes factor  $(g_J^2 - 1)^2 J(J+1)$  for ground-state multiplet  $J$  through the rare earths. If one normalizes the de Gennes line to the  $\text{Gd}_mM\text{In}_{3m+2}$  ( $M = \text{Rh}$  or  $\text{Ir}$ ,  $m = 1, 2$ )  $T_N$  values, the Sm-based  $T_N$  values sit on the line but the  $T_N$  values for the Nd-based and the magnetic Ce-based compounds are above the line (see Figs. 5 and 6). In addition, the evolution of the Néel temperature for the homologous  $RM\text{In}_5$  and  $R_2M\text{In}_8$  compounds compared to their cubic  $R\text{In}_3$  relatives, varies by

FIG. 6.  $T_N$  and  $c/a$  values plotted through the rare-earth series for the  $R_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ) compounds. The solid lines are the de Gennes factor  $[(g_J^2 - 1)^2 J(J+1)]$  of the rare earths normalized by the  $\text{Gd}_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ )  $T_N$  values and the dashed lines are a guide for the eye.

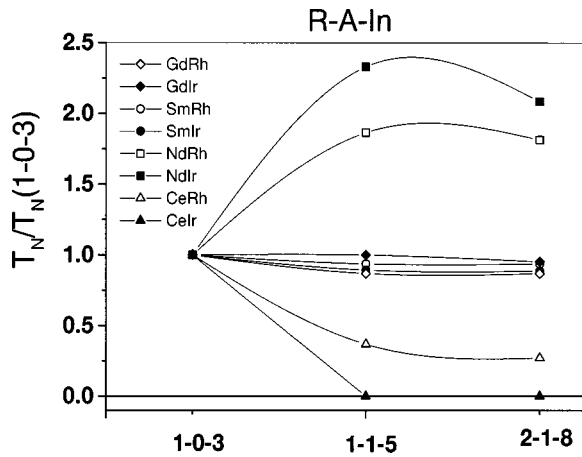

FIG. 7. Evolution of the normalized Néel temperatures for the Gd- and Sm-based compounds. For comparison, data for the homologous Ce- and Nd-based compounds and for cubic  $R\text{In}_3$  ( $R = \text{Ce, Nd, Sm, Gd}$ ), are also shown.

less than 10% for  $R = \text{Gd}$  and  $\text{Sm}$  while  $T_N$  is raised by a factor of 2 for the Nd-based tetragonal variants and is suppressed completely ( $M = \text{Ir}$ ) or to less than 0.5 of the  $\text{CeIn}_3$  value ( $M = \text{Rh}$ ) for the Ce-based homologous compounds (see Fig. 7).<sup>3,5</sup>

De Gennes scaling<sup>14</sup> does not take into account CEF, Kondo effects, and/or spatial dependence and anisotropic effects in the effective exchange parameter. Some of these effects are clearly present in the Ce-based and Nd-based homologues.<sup>1,3,5</sup> Therefore it is not a surprise that the  $T_N$  values for the Ce-based and Nd-based homologues do not follow a de Gennes scaling. Furthermore, our data for Gd- and Sm-based compounds suggest that anisotropic and/or CEF effects may decrease along the rare-earth series. The Sm-based compounds ( $\text{Sm}^{3+}$  has  $J = 5/2$ , identical to  $\text{Ce}^{3+}$ ) show smaller ratios  $\chi_{\text{easy}}/\chi_{\perp\text{easy}}$  ranging between 1.05 and 1.30 (see Fig. 2) while these ratios range from 1.20 to greater than 2 for the Ce-based analogues.<sup>3</sup> A possible explanation for this behavior may be related to the systematic decreasing

of  $c/a$  ratio through the rare-earth series (see Figs. 5 and 6) which may diminish the tetragonal character of the crystal-electric field and/or the magnetic anisotropy effects in the Sm case. The Gd-based compounds, which are expected to present small CEF due to the  $S$  character of the  $\text{Gd}^{3+}$  ( $S = 7/2$ ,  $L = 0$ ) ion, show only slight anisotropy in the magnetic susceptibility above  $T_N$  (see Fig. 1) and also small  $T_N$  evolution within the  $R_m M_n \text{In}_{3m+2n}$  ( $M = \text{Rh}$  or  $\text{Ir}$ ,  $m = 1, 2$ ;  $n = 0, 1$ ) compounds. Therefore the absence or reduction of Kondo, CEF effects and/or magnetic anisotropy for the  $(\text{Gd, Sm})M\text{In}_5$  and  $(\text{Gd, Sm})_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ) compounds may cause their magnetic properties to be roughly the same as their cubic relatives  $\text{GdIn}_3$  and  $\text{SmIn}_3$ . Further investigation in the evolution of the crystal-field parameters and the character of the magnetic state for  $RM\text{In}_5$  and  $R_2M\text{In}_8$  including heaviest rare earths (e.g.,  $R = \text{Dy, Er,}$  or  $\text{Yb}$ ) would be valuable in confirming our supposition.

## V. CONCLUSIONS

We have reported a new series of Gd- and Sm-based antiferromagnetic ( $T_N < 45$  K) compounds. Their low-temperature magnetic properties remain similar to their  $\text{SmIn}_3$  and  $\text{GdIn}_3$  cubic relatives. Comparisons among the present data and the magnetic properties of isostructural  $(\text{Ce, Nd})(\text{Rh, Ir})\text{In}_5$  and  $(\text{Ce, Nd})_2(\text{Rh, Ir})\text{In}_8$  and of de Gennes scaling as a function of rare earth in a given structure suggest that the reduction CEF effects and related magnetic anisotropy through the rare-earth series for the tetragonal variants may cause the magnetic properties of  $(\text{Gd, Sm})M\text{In}_5$  ( $\text{Gd, Sm})_2M\text{In}_8$  ( $M = \text{Rh}$  or  $\text{Ir}$ ) and their cubic relatives  $\text{GdIn}_3$  and  $\text{SmIn}_3$  to be nearly the same.
